- **C.3** Using the GUI
Preface

Acknowledgments

The first author is much indebted to H. B. Keller of the California Institute of Technology for his inspiration, encouragement and support. He is also thankful to AUTO users and research collaborators who have directly or indirectly contributed to its development, in particular, Jean Pierre Kernévez, UTC, Compiègne, France; Don Aronson, University of Minnesota, Minneapolis; and Hans Othmer, University of Utah. Material in this document related to the computation of connecting orbits was developed with Mark Friedman, University of Alabama, Huntsville. Also acknowledged is the work of Nguyen Thanh Long, Concordia University, Montreal, on the graphics program PLAUT and the pendula animation program. An earlier graphical user interface for AUTO on SGI machines was written by Taylor & Kevrekidis (1989). Special thanks are due to Sheila Shull, California Institute of Technology, for her cheerful assistance in the distribution of AUTO over a long period of time. Over the years, the development of AUTO has been supported by various agencies through the California Institute of Technology. Work on this updated version was supported by a general research grant from NSERC (Canada).

The development of HomCont has much benefitted from various pieces of help and advice from, among others, W.-J. Beyn, Universität Bielefeld, M. J. Friedman, University of Alabama, A. Rucklidge, University of Cambridge, M. Koper, University of Utrecht and C. J. Budd, University of Bristol. Financial support for collaboration was received from the U.K. Engineering and Physical Science Research Council and the Nuffield Foundation.
Chapter 1

Installing AUTO.

1.1 Typographical Conventions

This manual uses the following conventions.

<tr>
<td><strong>function</strong></td>
<td>This font is used for function names.</td>
</tr>
</tbody>
</table>

1.2 Installation.

The AUTO files are available via HTTP from [http://sourceforge.net/project/showfiles.php?group_id=21781](http://sourceforge.net/project/showfiles.php?group_id=21781).

<table>
<thead>
<tr>
<th>Package Type</th>
<th>Source File</th>
</tr>

<td>auto2000-0.9.8.zip</td>
</tr>
</tbody>
</table>

Below it is assumed that you are using the Unix shell **tcsh** or **bash** and that the file **auto2000-0.9.8.tar.Z** is in your main directory.

While in your main directory, enter the commands `uncompress auto2000-0.9.8.tar.Z`, followed by `tar xvfo auto2000-0.9.8.tar`. This will result in a directory **auto**, with one subdirectory, **auto/2000**. Type **cd auto/2000** to change directory to **auto/2000**. Then type `.configure`, to check your system for required compilers and libraries. Once the **configure** script has finished you may then type **make** to compile AUTO and its ancillary software. The **configure** script is designed to detect the details of your system which AUTO requires to compile successfully. If either the **configure** script or the **make** command should fail, you may assist the...
configure script by giving it various command line options. Please type 

```bash
./configure --help
```

for more details. Upon compilation, you may type `make clean` to remove unnecessary files.

There is a new CLUI under development which includes some of the capabilities of the old GUI and will eventually be the recommend way to run AUTO. More information on the CLUI may be found in Chapter 4. The new CLUI does not require any additional options to be passed to the configure script.

To run the new Command Line User Interface (CLUI) and the old command language you need to set your environment variables correctly. Assuming AUTO is installed in your home directory, the following commands set your environment variables so that you will be able to run the AUTO commands, and may be placed into your `.login`, `.profile`, or `.cshrc` file, as appropriate. If you are using a `sh` compatible shell, such as `sh`, `bash`, `ksh`, or `ash` enter the command

```bash
source $HOME/auto/2000/cmds/auto.env.sh
```

On the other hand, if you are using a `csh` compatible shell, such as `csh` or `tcsh`, enter the command `source $HOME/auto/2000/cmds/auto.env.csh`.

There is an old and unsupported Graphical User Interface (GUI) which requires the X-Window system and Motif, and it is not compiled by default. Note that AUTO can be very effectively run in Command Mode, i.e., the GUI is not strictly necessary. To compile AUTO with the old GUI, type `./configure --enable-gui` and then `make` in directory `auto/2000`.

The PostScript conversion command `@ps` will be enabled if the configure script detects the appropriate software, but you may have to enter the correct printer name in `auto/2000/cmds/@pr`.

To generate the on-line manual, type `make` in `auto/2000/doc`. To prepare AUTO for transfer to another machine, type `make superclean` in directory `auto/2000` before creating the `tar`-file. This will remove all executable, object, and other non-essential files, and thereby reduce the size of the package.

AUTO can be tested by typing `make > TEST &` in directory `auto/2000/test`. This will execute a selection of demos from `auto/2000/demos` and write a summary of the computations in the file `TEST`. The contents of `TEST` can then be compared to other test result files in directory `auto/2000/test`. Note that minor differences are to be expected due to architecture and compiler differences.

Some EISPACK routines used by AUTO for computing eigenvalues and Floquet multipliers are included in the package (Smith, Boyle, Dongarra, Garbow, Ikebe, Klema & Moler (1976)).

1.2.1 Installation on Mac OS X

AUTO runs on Mac OS X using the above instructions provided that you have the development tools installed. You do not need to run AUTO with an X server. To be able to plot, AUTO uses `pythonw` instead of `python`. This should happen automatically.

1.2.2 Installation on Windows

AUTO runs on Windows as above using the UNIX-like environment Cygwin (see [http://www.cygwin.com](http://www.cygwin.com)). You should have at least the default installation, `gcc`, `g77` or `gfortran`, `make`, and `python` installed. An X server is not necessary.
1.3 Restrictions on Problem Size.

There are size restrictions in the file `auto/2000/src/auto_c.h` on the following AUTO -constants: the effective number of equation parameters `NPAR`, and the number of stored branch points `NBIF` for algebraic problems. See Chapter 5 for the significance these constants. Their maxima are denoted by the corresponding constant followed by an X. For example, `NPARX` in `auto_c.h` denotes the maximum value of `NPAR`. If the maxima of `NBIF` is exceeded in an AUTO -run then a message will be printed. On the other hand, the maximum value of `NPAR`, if exceeded, may lead to unreported errors. Upon installation `NPARX=50`; it should never be decreased below that value; see also Section 6.1. Size restrictions can be changed by editing `auto_c.h`. This must be followed by recompilation by typing `make` in directory `auto/2000/src`.

Note that in certain cases the effective dimension may be greater than the user dimension. For example, for the continuation of folds, the effective dimension is $2 \text{NDIM}+1$ for algebraic equations, and $2 \text{NDIM}$ for ordinary differential equations, respectively. Similarly, for the continuation of Hopf bifurcations, the effective dimension is $3 \text{NDIM}+2$.

1.4 Compatibility with Older Versions.

There are two changes compared to early versions of AUTO 94: The user-supplied equations-files must contain the subroutine `pvls`. For an example of use of `pvls` see the demo `pvl` in Section 14.1. There is also a small change in the `q.xxx/s.xxx` data-file. If necessary, older AUTO 94 files can be converted using the `@@94to97` command; see Section A. Data files from AUTO 97 are fully compatible with AUTO 2000, but as AUTO 2000 is written in C user defined function files from AUTO 97, which are generally in Fortran, are ideally rewritten. This is not strictly necessary, however, as AUTO2000 has wrappers that can call Fortran code.

1.5 Parallel Version.

AUTO 2000 contains code which allows it to run in on various types of parallel computers. Namely, it can use either the Pthreads library for running on shared-memory multi-processors, or the MPI message passing library. When the `configure` script is run it will try to find the above two libraries, and if it is successful it will include their functionality into AUTO 2000. To force the `configure` script not to use either of the above libraries, one may type `./configure --without-mpi` or `./configure --without-pthreads`, and then type `make`. One may even preclude both by typing `./configure --without-mpi --without-pthreads` and then typing `make`. On the other hand, unless there is some particular difficulty, we recommend that that the `configure` script be used without arguments, since the parallel version of AUTO 2000 may easily be controlled, and even run in a serial mode, through the use of command line options at run time. The command line options are listed in Table 1.1.

For example, to run the AUTO 2000 executable `auto.exe` in serial mode you just type `auto.exe`. To run the same command in parallel using the Pthreads library on 4 processors you type `auto.exe -t both -# 4`. If you were to try and run the above command on a machine which did not have the Pthreads library, the command would exit with an error and inform you that the Pthreads library is not available.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-v</td>
<td>Give verbose output.</td>
</tr>
<tr>
<td>-m</td>
<td>Use the Message Passing Interface library for parallelization.</td>
</tr>
</tbody>
</table>
| -t     | Use the Pthreads library for parallelization. This option takes one of three arguments.  
  
  conpar parallelizes the condensation of parameters routine.  
  
  setubv parallelizes the Jacobian setup routine.  
  
  both parallelizes both routines.  
  
  In general the recommended option is 'both'. |
| -#     | The number of processing units to use (currently only used with the -t option). |

Table 1.1: Command line options.

Running the MPI version is somewhat more complex because of the fact that MPI normally uses some external program for starting the computational processes. The exact name and command line options of this external program depends on your MPI installation. A common name for this MPI external program is `mpirun`, and a common command line option which defines the number of computational processes is `-np`. Accordingly, if you wanted to run the MPI version of AUTO 2000 on four processors, with the above external program, you would type `mpirun -np 4 auto.exe -m`. Please see your local MPI documentation for more detail. As with the Pthreads library, if you were to try and run the above command on a machine which did not have MPI, the command would exit with an error and inform you that MPI is not available.

The commands in the `auto/2000/cmds` directory and described in Chapter 3 may be used with the parallel version as well, by setting the `AUTO_COMMAND_PREFIX` and `AUTO_COMMAND_ARGS` environment variables. For example, to the run AUTO 2000 in parallel using the Pthreads library on 4 processors just type `setenv AUTO_COMMAND_ARGS '-t both -# 4'` and then use the commands in `auto/2000/cmds` normally. To run AUTO 97 in parallel using the MPI library on 4 processors just type `setenv AUTO_COMMAND_ARGS '-m'` and `setenv AUTO_COMMAND_PREFIX `mpirun -np 4``, and then use the commands in `auto/2000/cmds` normally. The previous examples assumed you are using the `csh` shell or the `tcsh` shell, for other shells you should modify the commands appropriately.
Chapter 2
Overview of Capabilities.

2.1 Summary.
AUTO can do a limited bifurcation analysis of algebraic systems

\[ f(u, p) = 0, \quad f(\cdot, \cdot), u \in \mathbb{R}^n, \quad (2.1) \]

and of systems of ordinary differential equation (ODEs) of the form

\[ u'(t) = f(u(t), p), \quad f(\cdot, \cdot), u(\cdot) \in \mathbb{R}^n, \quad (2.2) \]

Here \( p \) denotes one or more free parameters.

It can also do certain stationary solution and wave calculations for the partial differential equation (PDE)

\[ u_t = Du_{xx} + f(u, p), \quad f(\cdot, \cdot), u(\cdot) \in \mathbb{R}^n, \quad (2.3) \]

where \( D \) denotes a diagonal matrix of diffusion constants. The basic algorithms used in the package, as well as related algorithms, can be found in Keller (1977), Keller (1986), Doedel, Keller & Kernévez (1991a), Doedel, Keller & Kernévez (1991b).

Below, the basic capabilities of AUTO are specified in more detail. Some representative demos are also indicated.

2.2 Algebraic Systems.
Specifically, for (2.1) the program can:

- Compute solution branches.
  (Demo ab; Run 1.)

- Locate branch points and automatically compute bifurcating branches.
  (Demo pp2; Run 1.)

- Locate Hopf bifurcation points and continue these in two parameters.
  (Demo ab; Runs 1 and 5.)
- Locate folds (limit points) and continue these in two parameters.
  (Demo ab; Runs 1,3,4.)

- Do each of the above for fixed points of the discrete dynamical system $u(k+1) = f(u(k), p)$
  (Demo dd2.)

- Find extrema of an objective function along solution branches and successively continue
  such extrema in more parameters.
  (Demo opt.)

### 2.3 Ordinary Differential Equations.

For the ODE (2.2) the program can:

- Compute branches of stable and unstable periodic solutions and compute the Floquet multipliers,
  that determine stability, along these branches. Starting data for the computation of periodic orbits
  are generated automatically at Hopf bifurcation points.
  (Demo ab; Run 2.)

- Locate folds, branch points, period doubling bifurcations, and bifurcations to tori, along
  branches of periodic solutions. Branch switching is possible at branch points and at period
  doubling bifurcations.
  (Demos tor, lor.)

- Continue folds and period-doubling bifurcations, in two parameters.
  (Demos plp, pp3.) The continuation of orbits of fixed period is also possible. This is the simplest
  way to compute curves of homoclinic orbits, if the period is sufficiently large.
  (Demo pp2.)

- Do each of the above for rotations, i.e., when some of the solution components are periodic
  modulo a phase gain of a multiple of $2\pi$.
  (Demo pen.)

- Follow curves of homoclinic orbits and detect and continue various codimension-2 bifurcations,
  using the HomCont algorithms of Champneys & Kuznetsov (1994), Champneys, Kuznetsov & Sandstede
  (1996).
  (Demos san, mnt, kpr, cir, she, rev.)

- Locate extrema of an integral objective functional along a branch of periodic solutions and
  successively continue such extrema in more parameters.
  (Demo ops.)

- Compute curves of solutions to (2.2) on $[0, 1]$, subject to general nonlinear boundary and
  integral conditions. The boundary conditions need not be separated, i.e., they may involve
  both $u(0)$ and $u(1)$ simultaneously. The side conditions may also depend on parameters.
  The number of boundary conditions plus the number of integral conditions need not equal
  the dimension of the ODE, provided there is a corresponding number of additional parameter
variables.
(Demos exp, int.)

- Determine folds and branch points along solution branches to the above boundary value problem. Branch switching is possible at branch points. Curves of folds can be computed in two parameters.
(Demos bvp, int.)

### 2.4 Parabolic PDEs.

For (2.3) the program can:

- Trace out branches of spatially homogeneous solutions. This amounts to a bifurcation analysis of the algebraic system (2.1). However, AUTO uses a related system instead, in order to enable the detection of bifurcations to wave train solutions of given wave speed. More precisely, bifurcations to wave trains are detected as Hopf bifurcations along fixed point branches of the related ODE

\[
\begin{align*}
    u'(z) &= v(z), \\
    v'(z) &= -D^{-1} \left[ c\, v(z) + f(u(z), p) \right],
\end{align*}
\]  

(2.4)

where \( z = x - ct \), with the wave speed \( c \) specified by the user.
(Demo wav; Run 2.)

- Trace out branches of periodic wave solutions to (2.3) that emanate from a Hopf bifurcation point of Equation 2.4. The wave speed \( c \) is fixed along such a branch, but the wave length \( L \), i.e., the period of periodic solutions to (2.4), will normally vary. If the wave length \( L \) becomes large, i.e., if a homoclinic orbit of Equation 2.4 is approached, then the wave tends to a solitary wave solution of (2.3).
(Demo wav; Run 3.)

- Trace out branches of waves of fixed wave length \( L \) in two parameters. The wave speed \( c \) may be chosen as one of these parameters. If \( L \) is large then such a continuation gives a branch of approximate solitary wave solutions to (2.3).
(Demo wav; Run 4.)

- Do time evolution calculations for (2.3), given periodic initial data on the interval \([0, L]\). The initial data must be specified on \([0, 1]\) and \( L \) must be set separately because of internal scaling. The initial data may be given analytically or obtained from a previous computation of wave trains, solitary waves, or from a previous evolution calculation. Conversely, if an evolution calculation results in a stationary wave then this wave can be used as starting data for a wave continuation calculation.
(Demo wav; Run 5.)

- Do time evolution calculations for (2.3) subject to user-specified boundary conditions. As above, the initial data must be specified on \([0, 1]\) and the space interval length \( L \) must be specified separately. Time evolution computations of (2.3) are adaptive in space and in time.
Discretization in time is not very accurate: only implicit Euler. Indeed, time integration of (2.3) has only been included as a convenience and it is not very efficient. (Demos pd1, pd2.)

- Compute curves of stationary solutions to (2.3) subject to user-specified boundary conditions. The initial data may be given analytically, obtained from a previous stationary solution computation, or from a time evolution calculation. (Demos pd1, pd2.)

In connection with periodic waves, note that (2.4) is just a special case of (2.2) and that its fixed point analysis is a special case of (2.1). One advantage of the built-in capacity of AUTO to deal with problem (2.3) is that the user need only specify $f$, $D$, and $c$. Another advantage is the compatibility of output data for restart purposes. This allows switching back and forth between evolution calculations and wave computations.

2.5 Discretization.

AUTO discretizes ODE boundary value problems (which includes periodic solutions) by the method of orthogonal collocation using piecewise polynomials with 2-7 collocation points per mesh interval (de Boor & Swartz (1973)). The mesh automatically adapts to the solution to equidistribute the local discretization error (Russell & Christiansen (1978)). The number of mesh intervals and the number of collocation points remain constant during any given run, although they may be changed at restart points. The implementation is AUTO-specific. In particular, the choice of local polynomial basis and the algorithm for solving the linearized collocation systems were specifically designed for use in numerical bifurcation analysis.
Chapter 3

How to Run AUTO.

3.1 User-Supplied Files.

The user must prepare the two files described below. This can be done with the GUI described in Chapter 4, or independently.

3.1.1 The equations-file xxx.c

A source file xxx.c containing the C subroutines func, stpnt, bcnd, icnd, fopt, and pvls. Here xxx stands for a user-selected name. If any of these subroutines is irrelevant to the problem then its body need not be completed. Examples are in auto/2000/demos, where, e.g., the file ab/ab.c defines a two-dimensional dynamical system, and the file exp/exp.c defines a boundary value problem. The simplest way to create a new equations-file is to copy an appropriate demo file. In GUI mode, this file can be directly loaded with the GUI-button Equations/New; see Section C.2.

Alternatively you can use a Fortran equations-file xxx.f (the same one used in AUTO 97). However, arrays in Fortran are 1-based as opposed to of the 0 based C-arrays. In particular, this affects the parameter array, where the period-parameter PAR(11) in Fortran corresponds to par[10] in C, and you need to add 1 to all fixed parameter indices mentioned in Chapters 5 and 15.

3.1.2 The constants-file c.xxx

AUTO-constants for xxx.c are normally expected in a corresponding file c.xxx. Specific examples include ab/c.ab and exp/c.exp in auto/2000/demos. See Chapter 5 for the significance of each constant.
3.2 User-Supplied Subroutines.

The purpose of each of the user-supplied subroutines in the file xxx.c is described below.

- **func**: defines the function \( f(u, p) \) in (2.1), (2.2), or (2.3).

- **stpnt**: This subroutine is called only if \( IRS=0 \) (see Section 5.8.5 for \( IRS \)), which typically is the case for the first run. It defines a starting solution \( (u, p) \) of (2.1) or (2.2). The starting solution should not be a branch point.
  
  (Demos \( ab, \ exp, \ frc, \ lor. \))

- **bend**: A subroutine \( bend \) that defines the boundary conditions.
  
  (Demo \( exp, \ kar. \))

- **icnd**: A subroutine \( icnd \) that defines the integral conditions.
  
  (Demos \( int, \ lin. \))

- **fopt**: A subroutine \( fopt \) that defines the objective functional.
  
  (Demos \( opt, \ ops. \))

- **pvls**: A subroutine \( pvls \) for defining “solution measures”.
  
  (Demo \( pvl. \))

3.3 Arguments of **stpnt**.

Note that the arguments of **stpnt** depend on the solution type:

- When starting from a fixed point or an analytically or numerically known space-dependent solution, **stpnt** must have four arguments, namely, \((\text{NDIM}, U, \text{PAR}, T)\). Here \( T \) is the independent space variable which takes values in the interval \([0, 1]\). \( T \) is ignored in the case of fixed points.
  
  (Demos \( exp \) and \( ab. \))

- Similarly, when starting from an analytically known time-periodic solution or rotation, the arguments of **stpnt** are \((\text{NDIM}, U, \text{PAR}, T)\), where \( T \) denotes the independent time variable which takes values in the interval \([0, 1]\). In this case one must also specify the period in \( \text{PAR}(11) \).
  
  (Demos \( frc, \ lor, \ pen. \))

- When using the \( @fc \) command (Section A) for conversion of numerical data, **stpnt** must have four arguments, namely, \((\text{NDIM}, U, \text{PAR}, T)\). In this case only the parameter values need to be defined in **stpnt**.
  
  (Demos \( lor \) and \( pen. \))
3.4 User-Supplied Derivatives.

If AUTO -constant JAC equals 0 then derivatives need not be specified in func, bcnd, icnd, and fopt; see Section 5.2.4. If JAC=1 then derivatives must be given. This may be necessary for sensitive problems, and is recommended for computations in which AUTO generates an extended system. Examples of user-supplied derivatives can be found in demos dd2, int, plp, opt, and ops.

3.5 Output Files.

AUTO writes four output-files:

- fort.6: A summary of the computation is written in fort.6, which usually corresponds to the window in which AUTO is run. Only special, labeled solution points are noted, namely those listed in Table 3.1. The letter codes in the Table are used in the screen output. The numerical codes are used internally and in the fort.7 and fort.8 output-files described below.

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BP</td>
<td>Branch point (algebraic systems)</td>
</tr>
<tr>
<td>LP</td>
<td>Fold (algebraic systems)</td>
</tr>
<tr>
<td>HB</td>
<td>Hopf bifurcation</td>
</tr>
<tr>
<td>UZ</td>
<td>User-specified regular output point</td>
</tr>
<tr>
<td>LP</td>
<td>Fold (differential equations)</td>
</tr>
<tr>
<td>BP</td>
<td>Branch point (differential equations)</td>
</tr>
<tr>
<td>PD</td>
<td>Period doubling bifurcation</td>
</tr>
<tr>
<td>TR</td>
<td>Torus bifurcation</td>
</tr>
<tr>
<td>EP</td>
<td>End point of branch; normal termination</td>
</tr>
<tr>
<td>MX</td>
<td>Abnormal termination; no convergence</td>
</tr>
</tbody>
</table>

Table 3.1: Solution Types.

- fort.7: The fort.7 output-file contains the bifurcation diagram. Its format is the same as the fort.6 (screen) output, but the fort.7 output is more extensive, as every solution point has an output line printed.

- fort.8: The fort.8 output-file contains complete graphics and restart data for selected, labeled solutions. The information per solution is generally much more extensive than that in fort.7. The fort.8 output should normally be kept to a minimum.

- fort.9: Diagnostic messages, convergence history, eigenvalues, and Floquet multipliers are written in fort.9. It is strongly recommended that this output be habitually inspected. The amount of diagnostic data can be controlled via the AUTO -constant IID; see Section 5.9.2.

The user has some control over the fort.6 (screen) and fort.7 output via the AUTO -constant IPLT (Section 5.9.3). Furthermore, the subroutine pvls can be used to define “solution measures”
which can then be printed by “parameter overspecification”; see Section 5.7.10. For an example see demo pvl.

The AUTO -commands @sv, @ap, and @df can be used to manipulate the output-files fort.7, fort.8, and fort.9. Furthermore, the AUTO -command @lb can be used to delete and relabel solutions simultaneously in fort.7 and fort.8. For details see Section A.

The graphics program PLAUT can be used to graphically inspect the data in fort.7 and fort.8; see Chapter B.
Chapter 4

Command Line User Interface.

4.1 Typographical Conventions

This chapter uses the following conventions. All code examples will be in the following font.

\begin{center}
\begin{tabular}{|l|}
\hline
\texttt{AUTO> copydemo("ab")}  \\
\texttt{Copying demo ab ... done} \\
\hline
\end{tabular}
\end{center}

To distinguish commands which are typed to the Unix shell from those which are typed to the AUTO 2000 command line user interface (CLUI) we will use the following two prompts.

\begin{center}
\begin{tabular}{|l|}
\hline
\texttt{>}  Commands which follow this prompt are for the Unix shell. \\
\texttt{AUTO>}  Commands which follow this prompt are for the AUTO 2000 CLUI. \\
\hline
\end{tabular}
\end{center}

4.2 General Overview.

The AUTO 2000 command line user interface (CLUI) is similar to the command language described in Section A in that it facilitates the interactive creating and editing of equations-files and constants-files. It differs from the other command language in that it is based on the object-oriented scripting language Python (see Lutz (1996)) and provides extensive programming capabilities. This chapter will provide documentation for the AUTO 2000 CLUI commands, but is not intended as a tutorial for the Python language. We will attempt to make this chapter self contained by describing all Python constructs that we use in the examples, but for more extensive documentation on the Python language, including tutorials and pointers to further documentation, please see Lutz (1996) or the web page http://www.python.org which contains an excellent tutorial at http://www.python.org/doc/current/tut/tut.html.

To use the CLUI for a new equation, change to an empty directory. For an existing equations-file, change to its directory. (\textit{Do not activate the CLUI in the directory auto/2000 or in any of its subdirectories.}) Then type

\begin{center}
\texttt{auto.}
\end{center}

If your command search path has been correctly set (see Section 1.2), this command will start the AUTO 2000 CLUI interactive interpretor and provide you with the AUTO 2000 CLUI prompt.
Figure 4.1: Typing `auto` at the Unix shell prompt starts the AUTO 2000 CLUI.

In addition to the examples in the following sections there are several example scripts which can be found in `auto/2000/demos/python` and are listed in Table 4.1. These scripts are fully annotated and provide good examples of how AUTO 2000 CLUI scripts are written. The scripts in `auto/2000/demos/python/n-body` are especially lucid examples and perform various related parts of a calculation involving the gravitational N-body problem. Scripts which end in the suffix `.auto` are called “basic” scripts and can be run by typing `auto scriptname.auto`. The scripts show in Section 4.3 and Section 4.5 are examples of basic scripts. Scripts which end in the suffix `.xauto` are called “expert” scripts and can be run by typing `autox scriptname.xauto`. More information on expert scripts can be found in Section 4.6. See the README file in that directory for more information.

### 4.3 First Example

We begin with a simple example of the AUTO 2000 CLUI. In this example we copy the `ab` demo from the AUTO 2000 installation directory and run it. For more information on the `ab` demo see Section 7.2. The commands listed in Table 4.2 will copy the demo files to your work directory and run the first part of the demo. The results of running these commands are shown in Figure 4.2.

Let us examine more closely what action each of the commands performs. First, `copydemo('ab')` (Section 4.13.7 in the reference) copies the files in `$AUTO_DIR/demo/ab` into the work directory.

Next, `load(equation='ab')` (Section 4.13.33 in the reference) informs the AUTO 2000 CLUI that the name of the user defined function file is `ab.c`. The command `load` is one of the most commonly used commands in the AUTO 2000 CLUI, since it reads and parses the user files which are manipulated by other commands. The AUTO 2000 CLUI stores this setting until it is changed by a command, such as another `load` command. The idea of storing information is one of the ideas that sets the CLUI apart from the command language described in Section A.

Next, `load(constants='ab.1')` parses the AUTO constants file `c.ab.1` and reads it into memory. Note that changes to the file `c.ab.1` after it has been loaded in will not be used by AUTO 2000 unless it is loaded in again after the changes are made.

Finally, `run()` (Section 4.13.31 in the reference) uses the user defined functions loaded by the `load(equation='ab')` command, and the AUTO constants loaded by the `load(constants='ab.1')` to run AUTO 2000.

Figure 4.2 showed two of the file types that the `load` command can read into memory, namely the user defined function file and the AUTO constants file (Section 3.1). There are two other files types that can be read in using the `load` command, and they are the restart solution file (Section 3.5) and the HomCont parameter file (Section 15.2).

```

Figure 4.2: Typing `auto` at the Unix shell prompt starts the AUTO 2000 CLUI. The rest of the commands are interpreted by the AUTO 2000 CLUI.
Note that the name given to the load command is not the same as the filename which is read in, for example `load(constants='ab.1')` reads in the file `c.ab.1`. This difference is a result of the automatic transformation of the filenames by the AUTO 2000 CLUI into the standard names used by AUTO 2000. The standard filename transformations are shown in Table 4.3.

<table>

</tbody>
</table>

Table 4.3: This table shows the standard AUTO 2000 CLUI filename translations. In `load` and `run` commands either the long name or the short name may be used for loading the appropriate files.

Since the `load` command is so common, there are various shorthand versions of it. First, there are short versions of the various arguments as shown in Table 4.3. For example, the command `load(constants='ab.1')` can be shortened to `load(c='ab.1')`. Next, several different files may be loaded at once using the same `load` command. For example, the two commands in Figure 4.3 have the same effect as the single command in Figure 4.4.

```
AUTO> load(e='ab')
Runner configured
AUTO> load(c='ab.1')
Runner configured
```

Figure 4.3: Loading two files individually.

```
AUTO> load(e='ab',c='ab.1')
Runner configured
```

Figure 4.4: Loading two files at the same time.

Also, since it is common that several files will be loaded that have the same base name `load('ab')` performs the same action as `load(e='ab',c='ab',s='ab',h='ab')`. Note, for the command `load('ab')` it is only required that `ab.c` and `c.ab` exist; `s.ab` and `h.ab` are optional, and if they do not exist, no error message will be given.

### 4.4 Scripting

Section 4.3 showed commands being interactively entered at the AUTO 2000 CLUI prompt, but since the AUTO 2000 CLUI is based on Python one has the ability to write scripts for performing
sequences of commands automatically. A Python script is very similar to the interactive mode shown in Section 4.3 except that the commands are placed in a file and read all at once. For example, if the commands from Figure 4.2 where placed into the file demo1.auto, in the format shown in Figure 4.5, then the commands could be run all at once by typing `auto demo1.auto`. See Figure 4.6 for the full output.

```
copydemo('ab')
load(equation='ab')
load(constants='ab.1')
run()
```

Figure 4.5: The commands from Figure 4.2 and they would appear in a AUTO 2000 CLUI script file. The source for this script can be found in `$AUTO_DIR/demos/python/demo1.auto`.

### 4.5 Second Example

In Section 4.3 we showed a very simple AUTO 2000 CLUI script, in this Section we will describe a more complex example, which introduces several new AUTO 2000 CLUI commands as well as some basic Python constructs for conditionals and looping. We will not provide an exhaustive reference for the Python language, but only the very basics. For more extensive documentation we refer the reader to Lutz (1996) or the web page [http://www.python.org](http://www.python.org). In this section we will describe each line of the script in detail, and the full text of the script is in Figure 4.7.

The script begins with a section, extracted into Figure 4.8, which performs a task identical to that shown in Figure 4.2 except that the shorthand discussed in Section 4.3 is used for the `ld` command.

The next section of the script, extracted into Figure 4.9, introduces three new AUTO 2000 CLUI commands. First, `sv('bvp')` (Section 4.13.6 in the reference) saves the results of the AUTO 2000 run into files using the base name `bvp` and the filename extensions in Table 4.3. For example, in this case the bifurcation diagram file `fort.7` will be saved as `b.bvp`, the solution file `fort.8` will be saved as `s.bvp`, and the diagnostics file `fort.9` will be saved as `d.bvp`. Next, `ld(s='bvp')` loads the solution file `s.bvp` into memory so that it can be used by AUTO 2000 for further calculations.

Up to this point all of the commands presented have had analogs in the command language discussed in Section A, and the AUTO 2000 CLUI has been designed in this way to make it easy for users to migrate from the old command language to the AUTO 2000 CLUI. The next command, namely `data = sl('bvp')` (Section 4.13.19 in the reference) is the first command which has no analog in the old command language. The command `sl('bvp')` parses the file `s.bvp` and returns a python object which encapsulates the information contained in the file and presents it to the user in an easy to use format. Accordingly, the command `data = sl('bvp')` stores this easy to use representation of the object in the Python variable `data`. Note, variables in Python are different from those in languages such as C in that their type does not have to be declared before they are created. Finally, `ch("NTST",50)` (Section 4.13.32 in the reference) changes the `NTST` value to 50 (see Section 5.2.1). To be precise, the command `ch("NTST",50)`
Figure 4.6: This Figure starts by listing the contents of the `demo1.auto` file using the Unix `cat` command. The file is then run through the AUTO 2000 CLUI by typing `auto demo1.auto` and the output is shown.

</tbody>
</table>

Total Time 8.740E-02
ab ... done

The next section of the script, extracted into Figure 4.10, shows as example of looping and conditionals in an AUTO 2000 CLUI script. The first line `for solution in data:` is the Python syntax for loops. The `data` variable was defined in Figure 4.9 to be the parsed version of an AUTO 2000 `fort.8` file, and accordingly contains a list of the solutions from the `fort.8` file. The command `for solution in data:` is used to loop over all solutions in the `data` variable by setting the variable `solution` to be one of the solutions in `data` and then calling the rest of the code in the block.

Python differs from most other computer languages in that blocks of code are not defined by some delimiter, such as `{}` in C, but by indentation. In Figure 4.7 the commands `plot('bvp')` and `wait()` are not part of the loop, because they are indented differently. This can be confusing first time users of Python, but it has the advantage that the code is forced to have a consistent indentation style.

The next command in the script, `if solution["Type name"] == "BP":` is a Python condi-
Figure 4.7: This Figure shows a more complex AUTO 2000 CLUI script. The source for this script can be found in $AUTO_DIR/demos/python/demo2.auto.

```python

copydemo('bvp')
ld('bvp')
run()
sv('bvp')
ld(s='bvp')
data = sl('bvp')
ch("NTST",50)
for solution in data:
    if solution["Type name"] == "BP":
        ch("IRS", solution["Label"])  
        ch("ISW", -1)
        # Compute forward
        run()
        ap('bvp')
        # Compute back
        ch("DS",-pr("DS"))
        run()
        ap('bvp')

plot('bvp')
wait()
```

Figure 4.8: The first part of the complex AUTO 2000 CLUI script.

```python

copydemo('bvp')
ld('bvp')
run()
```

Figure 4.9: The second part of the complex AUTO 2000 CLUI script.

```python

sv('bvp')
ld(s='bvp')
data = sl('bvp')
ch("NTST",50)
```
It examines the contents of the variable `solution` (which is one of the entries in the array of solutions `data`) and checks to see if the condition `solution['Type name'] == "BP"` holds. For parsed `fort.8` files, `Type name BP` corresponds to a bifurcation point. Accordingly, the function of this loop and conditional is to examine every solution in the `fort.8` file and run the following commands if the solution is a bifurcation point.

The next line is `ch("IRS", solution["Label"])` which changes the “in memory” version of the AUTO 2000 constants file to set IRS (see Section 5.8.5) equal to the label of the bifurcation point. We then use `ch("ISW", -1)` to change the AUTO 2000 constant ISW to -1, which indicates a branch switch (see Section 5.8.3).

We then use a `run()` command to perform the calculation of the bifurcating branch and then append the data to the `s.bvp`, `b.bvp`, and `d.bvp` files with the `ap('bvp')` command (Section 4.13.1 in the reference). In addition, as can be seen in Figure 4.10, the # character is the Python comment character. When the Python interpreter encounters a # character it ignores everything from that character to the end of the line.

Finally, we use `ch("DS",-pr("DS"))` to change the AUTO 2000 initial step size from positive to negative, which allows us to compute the bifurcating branch in the other direction (see Section 5.5.1). Running the AUTO 2000 calculation with the `run()` command and appending the data the appropriate files with the `ap('bvp')` command completes the body of the loop.

```python
for solution in data:
    if solution["Type name"] == "BP":
        ch("IRS", solution["Label"])  
        ch("ISW", -1)
        # Compute forward
        run()
        ap('bvp')
        # Compute back
        ch("DS",-pr("DS"))
        run()
        ap('bvp')
```

Figure 4.10: The second part of the complex AUTO 2000 CLUI script.

Now that the section of script shown in Figure 4.10 has finished computing the bifurcation diagram, the command `plot('bvp')` brings up a plotting window (Section 4.13.20 in the reference), and the command `wait()` causes the AUTO 2000 CLUI to wait for input. You may now exit the AUTO 2000 CLUI by pressing any key in the window in which you started the AUTO 2000 CLUI.

### 4.6 Extending the AUTO 2000 CLUI

The code in Figure 4.7 performed a very useful and common procedure, it started an AUTO 2000 calculation and performed additional continuations at every point which AUTO 2000 detected as a bifurcation. Unfortunately, the script as written can only be used for the `bvp` demo. In this section we will generalize the script in Figure 4.7 for use with any demo, and demonstrate how it can
be imported back into the interactive mode to create a new command for the AUTO 2000 CLUI. Several examples of such “expert” scripts can be found in `auto/2000/demos/python/n-body`.

Just as loops and conditionals can be used in Python, one can also define functions. For example, Figure 4.11 is a functional version of script from Figure 4.7. The changes are actually quite minor. The first line, `from AUTOclui import *`, includes the definitions of the AUTO 2000 CLUI commands, and must be included in all AUTO 2000 CLUI scripts which define functions. The next line, `def myRun(demo):`, begins the function definition, and creates a function named `myRun` which takes one argument `demo`. The rest of the script is the same except that it has been indented to indicate that it is part of the function definition, and all occurrences of string `'bvp'` have been replaced with the variable `demo`. Finally we have added a line `myRun('bvp')` which actually calls the function we have created and runs the same computation as the original script.

```python
from AUTOclui import *

def myRun(demo):
    
copydemo(demo)

ld(demo)
run()
sv(demo)
ld(s=demo)
data = sl(demo)
ch("NTST",50)
for solution in data:
    if solution["Type name"] == "BP":
        ch("IRS", solution["Label"])
        ch("ISW", -1)
        # Compute forward
        run()
ap(demo)
        # Compute back
        ch("DS",-pr("DS"))
        run()
ap(demo)

plot(demo)
wait()

myRun('bvp')
```

Figure 4.11: This Figure shows a complex AUTO 2000 CLUI script written as a function. The source for this script can be found in `$AUTO_DIR/demos/python/userScript.xauto`.

While the script in Figure 4.11 is only slightly different then the one showed in Figure 4.7 it is much more powerful. Not only can it be used as a script for running any demo by modifying
the last line, it can be read back into the interactive mode of the AUTO 2000 CLUI and used to create a new command, as in Figure 4.12. First, we create a file called userScript.py which contains the script from Figure 4.11, with one minor modification. We want the function only to run when we use it interactively, not when the file userScript.py is read in, so we remove the last line where the function is called. We start the AUTO 2000 CLUI with the Unix command auto, and once the AUTO 2000 CLUI is running we use the command from userScript import *, to import the file userScript.py into the AUTO 2000 CLUI. The import command makes all functions in that file available for our use (in this case myRun is the only one). It is important to note that from userScript import * does not use the .py extension on the file name. After importing our new function, we may use it just like any other function in the AUTO 2000 CLUI, for example by typing myRun('bvp').

4.7 Bifurcation Diagram Files

Using the commandParseDiagramFile command (Section 4.13.18 in the reference) the user can parse and read into memory an AUTO 2000 bifurcation diagram file. For example, the command commandParseDiagramFile('ab') would parse the file b.ab (if you are using the standard filename translations from Table 4.3) and return an object which encapsulates the bifurcation diagram in an easy to use form.

The object returned by the commandParseDiagramFile is a list of all of the solutions in the appropriate bifurcation diagram file, and each solution is a Python dictionary with entries for each piece of data for the solution. For example, the sequence of commands in Figure 4.13, prints out the label of the first solution in a bifurcation diagram. The queriable parts of the object are listed in Table 4.4.

The individual elements of the array may be accessed in two ways, either by index of the solution using the [] syntax or by label number using the () syntax. For example, assume that the parsed object is contained in a variable data. The first solution may be accessed using the command data[0], while the solution with label 57 may be accessed using the command data(57).

This class has two methods that are particularly useful for creating data which can be used in other programs. First, there is a method called toArray which takes a bifurcation diagram and returns a standard Python array. Second, there is a method called writeRawFilename which will create a standard ASCII file which contains the bifurcation diagram. For example, we again assume that the parsed object is contained in a variable data. If one wanted to have the bifurcation diagram returned as a Python array one would type data.toArray(). Similarly, if one wanted to write out the bifurcation diagram to the file outputFile one would type data.writeRawFilename('outputfile').

4.8 Solution Files

Using the commandParseSolutionFile command (Section 4.13.19 in the reference) the user can parse and read into memory an AUTO 2000 bifurcation solution file. For example, the command commandParseSolutionFile('ab') would parse the file b.ab (if you are using the standard file-
```python
> cp \$AUTO\_DIR/python/demo/userScript.py .
> ls
userScript.py
> cat userScript.py
# This is an example script for the AUTO2000 command line user
# interface. See the "Command Line User Interface" chapter in the
# manual for more details.
from AUTOclui import *

def myRun(demo):
    
    copydemo(demo)
    ld(demo)
    run()
    sv(demo)
    ld(s=demo)
    data = sl(demo)
    ch("NTST",50)
    for solution in data:
        if solution["Type name"] == "BP":
            ch("IRS", solution["Label"])
            ch("ISW", -1)
            # Compute forward
            run()
            ap(demo)
            # Compute back
            ch("DS",-pr("DS"))
            run()
            ap(demo)
    
    plot(demo)
    wait()

name translations from Table 4.3) and return an object which encapsulates the bifurcation solution in a easy to use form.

The object returned by the command ParseSolutionFile is a list of all of the solutions in the appropriate bifurcation solution file, and each solution is a Python dictionary with entries for each piece of data for the solution. For example, the sequence of commands in Figure 4.14, prints out the label of the first solution in a bifurcation solution. The queriable parts of the object are listed in Table 4.6.

```
AUTO> data=sl()
Parsed file: fort.8
AUTO> print data[0]
'Branch number': 2
'ISW': 1
'Label': 6
'NCOL': 0
'NTST': 0
'Parameters': [0.0, 14.0, 2.0, 0.0, 0.0, 0.0]
'Point number': 1
'Type name': 'EP'
'Type number': 9
'T': [0.0, 14.0, 2.0, 0.0, 0.0, 0.0]
'parameters': [0.0, 14.0, 2.0, 0.0, 0.0, 0.0]
AUTO> print data[0]['Label']
6
AUTO> data[0]['data'][0]
{'t': 0.0, 'u': [0.0, 0.0]}
```

Figure 4.14: This figure shows an example of parsing a bifurcation solution. The first command, `data=sl('ab')`, reads in the bifurcation solution and puts it into the variable `data`. The second command, `print data[0]` prints out all of the data about the first solution in the list. The third command, `print data[0]['Label']`, prints out the label of the first point. The last command prints the value of the solution at the first point of the first solution.

The individual elements of the array may be accessed in two ways, either by the index of the solution using the [] syntax or by label number using the () syntax. For example, assume that the parsed object is contained in a variable `data`. The first solution may be accessed using the command `data[0]`, while the solution with label 57 may be accessed using the command `data(57).

This class has two methods that are particularly useful for creating data which can be used in other programs. First, there is a method called `toArray` which takes a solution and returns a standard Python array. Second, there is a method called `writeRawFilename` which will create a standard ASCII file which contains the solution. The first element of each row will be the 't' value and the following elements will be the values of the components at that 't' value. For example, we again assume that the parsed object is contained in a variable `data`. If one wanted to have the solution with label 57 returned as a Python array one would type
<table>

</table>

Table 4.6: This table shows the strings that can be used to query a bifurcation solution object and their meanings.
data(57).toArray(). Similarly, if one wanted to write out the solution to the file `outputfile`
one would type `data(57).writeRawFilename('outputfile')`.

### 4.9 The `.autorc` File

Much of the default behavior of the AUTO 2000 CLUI can be controlled by the `.autorc` file. The
`.autorc` file can exist in either the main AUTO 2000 directory, the users home directory, or the
current directory. For any option which is defined in more then one file, the `.autorc` file in the
current directory (if it exists) takes precedence, followed by the `.autorc` file in the users home
directory (if it exists), and then the `.autorc` file in the main AUTO 2000 directory. Hence, options
may be defined on either a per directory, per user, or global basis.

The first section of the `.autorc` file begins with the line `[AUTO_command_aliases]` and this
section defines short names, or aliases, for the AUTO 2000 CLUI commands. Each line thereafter
is a definition of a command, similar to `branchPoint =commandQueryBranchPoint`. The right
hand side of the assignment is the internal AUTO 2000 CLUI name for the command, while the
left hand side is the desired alias. Aliases and internal names may be used interchangeably, but
the intention is that the aliases will be more commonly used. A default set of aliases is provided,
and these aliases will be used in the examples in the rest of this Chapter. The default aliases are
listed in the reference in Section 4.13.

`NOTE: Defaults for the plotting tool may be included in the .autorc file as well. The docu-
mentation for this is under development, but the file $AUTO_DIR/.autorc contains examples of
how these options may be set.`

### 4.10 Two Dimensional Plotting Tool

The two dimensional plotting tool can be run by using the command `plot()` to plot the files
`fort.7` and `fort.8` after a calculation has been run, or using the command `plot('foo')` to plote
the data in the files `s.foo` and `b.foo`.

The menu bar provides two buttons. The File button brings up a menu which allows the
user to save the current plot as a Postscript file or to quit the plotter. The Options button allows
the plotter configuration options to be modified. The available options are decribed in Table 4.7.
In addition, the options can be set from within the CLUI. For example, the set of commands
in Figure 4.15 shows how to create a plotter and change its background color to black. The
demo script auto/2000/demo/python/plotter.py contains several examples of changing options in
plotters.

Pressing the right mouse button in the plotting window brings up a menu of buttons which
control several aspects of the plotting window. The top two toggle buttons control what func-
tion the left button performs. The print value button causes the left button to print out the
numerical value underneath the pointer when it is clicked. When zoom button is checked the left
mouse button may be held down to create a box in the plot. When the left button is released the
plot will zoom to the selected portion of the diagram. The unzoom button returns the diagram
to the default zoom. The Postscript button allows the user to save the plot as a Postscript file.
The Configure... button brings up the dialog for setting configuration options.
Figure 4.15: This example shows how a plotter is created, and how the background color may be changed to black. All other configuration options are set similarly. Note, the above commands assume that the files fort.7 and fort.8 exist in the current directory.

<table>
<thead>
<tr>
<th>Query string</th>
<th>Meaning</th>

</tr>
</tbody>
</table>
symbol_color | The color to use for the marker symbols.
tick_label_template | A string which defines the format of the tick labels.
tick_length | The length of the tick marks.
torus_symbol | The symbol to use for torus bifurcation points.
type | The type of the plot, either “solution” or “bifurcation”.
user_point_symbol | The symbol to use for user defined output points.
xlabel | The label for the x-axis.
xmargin | The margin between the graph and the right and left edges.
xticks | The number of ticks on the x-axis.
ylabel | The label for the y-axis.
ymargin | The margin between the graph and the top and bottom edges.
yticks | The number of ticks on the y-axis.

Table 4.7: This table shows the options that can be set for the AUTO 2000 CLUI two dimensional plotting window and their meanings.

### 4.11 Three Dimensional Plotting Tool

*NOTE: the documentation in this section is under development.*

The AUTO 2000 three dimensional plotting tool can use DataViewer or OpenInventor for rendering three dimensional representations of bifurcation diagrams and solutions and is under active development. Neither DataViewer nor OpenInventor are provided with AUTO 2000 and must be downloaded separately. If you are interested in the three dimensional plotting tool please contact redrod@acm.org.
## 4.12 Quick Reference

In this section we have created a table of all of the AUTO 2000 CLUI commands, their abbreviations, and a one line description of what function they perform. Each command may be entered using its full name or any of its aliases.

<table>

4.13  Reference

4.13.1  commandAppend

Purpose
Append data files.

Description
Type commandAppend(‘xxx’) to append the output-files fort.7, fort.8, fort.9, to existing data-files s.xxx, b.xxx, and d.xxx (if you are using the default filename templates). Type commandAppend(‘xxx’,’yyy’) to append existing data-files s.xxx, b.xxx, and d.xxx to data-files s.yyy, b.yyy, and d.yyy (if you are using the default filename templates).

Aliases
ap append

4.13.2  commandCat

Purpose
Print the contents of a file

Description
Type 'commandCat xxx' to list the contents of the file 'xxx'. This calls the Unix function 'cat' for reading the file.

Aliases
cat
4.13.3 commandCd

**Purpose**

Change directories.

**Description**

Type 'commandCd xxx' to change to the directory 'xxx'. This command understands both shell variables and home directory expansion.

**Aliases**

cd

4.13.4 commandClean

**Purpose**

Clean the current directory.

**Description**

Type commandClean() to clean the current directory. This command will delete all files of the form fort.*, *.o, and *.exe.

**Aliases**

clean cl
4.13.5 commandCopyAndLoadDemo

Purpose

Copy a demo into the current directory and load it.

Description

Type commandCopyAndLoadDemo('xxx') to copy all files from auto/2000/demos/xxx to the current user directory. Here 'xxx' denotes a demo name; e.g., 'abc'. Note that the 'dm' command also copies a Makefile to the current user directory. To avoid the overwriting of existing files, always run demos in a clean work directory. NOTE: This command automatically performs the commandRunnerLoadName command as well.

Aliases

dm demo

4.13.6 commandCopyDataFiles

Purpose

Copy data files.

Description

Type commandCopyDataFiles('xxx','yyy') to copy the data-files c.xxx, d.xxx, b.xxx, and h.xxx to c.yyy, d.yyy, b.yyy, and h.yyy (if you are using the default filename templates).

Aliases

copy cp
4.13.7 commandCopyDemo

**Purpose**

Copy a demo into the current directory.

**Description**

Type commandCopyDemo(‘xxx’) to copy all files from auto/2000/demos/xxx to the current user directory. Here 'xxx' denotes a demo name; e.g., 'abc'. Note that the 'dm' command also copies a Makefile to the current user directory. To avoid the overwriting of existing files, always run demos in a clean work directory.

**Aliases**

copydemo

4.13.8 commandCopyFortFiles

**Purpose**

Save data files.

**Description**

Type commandCopyFortFiles('xxx') to save the output-files fort.7, fort.8, fort.9, to b.xxx, s.xxx, d.xxx (if you are using the default filename templates). Existing files with these names will be overwritten.

**Aliases**

sv save
4.13.9  commandCreateGUI

**Purpose**

Show AUTOs graphical user interface.

**Description**

Type commandCreateGUI() to start AUTOs graphical user interface.

NOTE: This command is not implemented yet.

**Aliases**

gui

4.13.10  commandDeleteDataFiles

**Purpose**

Delete data files.

**Description**

Type commandDeleteDataFiles('xxx') to delete the data-files d.xxx, b.xxx, and s.xxx (if you are using the default filename templates).

**Aliases**

delete dl
4.13.11 commandDeleteFortFiles

**Purpose**

Clear the current directory of fort files.

**Description**

Type `commandDeleteFortFiles()` to clean the current directory. This command will delete all files of the form `fort.*`.

**Aliases**

df deletefort

4.13.12 commandDouble

**Purpose**

Double a solution.

**Description**

Type `commandDouble()` to double the solution in ’fort.7’ and ’fort.8’.
Type `commandDouble(’xxx’)` to double the solution in b.xxx and s.xxx (if you are using the default filename templates).

**Aliases**

double db
4.13.13 commandInteractiveHelp

Purpose
Get help on the AUTO commands.

Description
Type 'help' to list all commands with a online help. Type 'help xxx' to get help for command 'xxx'.

Aliases
man help

4.13.14 commandLs

Purpose
List the current directory.

Description
Type 'commandLs' to run the system 'ls' command in the current directory. This command will accept whatever arguments are accepted by the Unix command 'ls'.

Aliases
ls
4.13.15  commandMoveFiles

Purpose
Move data-files to a new name.

Description
Type commandMoveFiles(‘xxx’,’yyy’) to move the data-files b.xxx, s.xxx, d.xxx, and c.xxx to b.yyy, s.yyy, d.yyy, and c.yyy (if you are using the default filename templates).

Aliases
move mv

4.13.16  commandParseConstantsFile

Purpose
Get the current continuation constants.

Description
Type commandParseConstantsFile(‘xxx’) to get a parsed version of the constants file c.xxx (if you are using the default filename templates).

Aliases
cn constantsget
4.13.17  commandParseDiagramAndSolutionFile

Purpose

Parse both bifurcation diagram and solution.

Description

Type commandParseDiagramAndSolutionFile(‘xxx’) to get a parsed version of the diagram file b.xxx and solution file s.xxx (if you are using the default filename templates).

Aliases

bt diagramandsolutionget

4.13.18  commandParseDiagramFile

Purpose

Parse a bifurcation diagram.

Description

Type commandParseDiagramFile(‘xxx’) to get a parsed version of the diagram file b.xxx (if you are using the default filename templates).

Aliases

dg diagramget
4.13.19 commandParseSolutionFile

Purpose

Parse solution file:

Description

Type commandParseSolutionFile(‘xxx’) to get a parsed version of the solution file s.xxx (if you are using the default filename templates).

Aliases

sl solutionget

4.13.20 commandPlotter

Purpose

2D plotting of data.

Description

Type commandPlotter(‘xxx’) to run the graphics program for the graphical inspection of the data-files b.xxx and s.xxx (if you are using the default filename templates). The return value will be the handle for the graphics window.

Type commandPlotter() to run the graphics program for the graphical inspection of the output-files ‘fort.7’ and ‘fort.8’. The return value will be the handle for the graphics window.

Aliases

p2 pl plot
4.13.21  commandPlotter3D

Purpose

3D plotting of data.

Description

Type commandPlotter3D('xxx') to run the graphics program for the graphical inspection of the data-files b.xxx and s.xxx (if you are using the default filename templates). The return value will be the handle for the graphics window.

Type commandPlotter3D() to run the graphics program for the graphical inspection of the output-files 'fort.7' and 'fort.8'. The return value will be the handle for the graphics window.

Aliases

plot3 p3

4.13.22  commandQueryBranchPoint

Purpose

Print the "branch-point function".

Description

Type commandQueryBranchPoint() to list the value of the "branch-point function" in the output-file fort.9. This function vanishes at a branch point.

Type commandQueryBranchPoint('xxx') to list the value of the "branch-point function" in the info file 'd.xxx'.

Aliases

br bp branchpoint
4.13.23 commandQueryEigenvalue

Purpose
Print eigenvalues of Jacobian (algebraic case).

Description
Type commandQueryEigenvalue() to list the eigenvalues of the Jacobian in fort.9. (Algebraic problems.)
Type commandQueryEigenvalue('xxx') to list the eigenvalues of the Jacobian in the info file 'd.xxx'.

Aliases
eigenvalue ev eg

4.13.24 commandQueryFloquet

Purpose
Print the Floquet multipliers.

Description
Type commandQueryFloquet() to list the Floquet multipliers in the output-file fort.9. (Differential equations.)
Type commandQueryFloquet('xxx') to list the Floquet multipliers in the info file 'd.xxx'.

Aliases
fl floquet
4.13.25  commandQueryHopf

Purpose

Print the value of the “Hopf function”.

Description

Type commandQueryHopf() to list the value of the “Hopf function” in the output-file fort.9. This function vanishes at a Hopf bifurcation point.
Type commandQueryHopf(‘xxx’) to list the value of the “Hopf function” in the info file ’d.xxx’.

Aliases

hb hp hopf lp

4.13.26  commandQueryIterations

Purpose

Print the number of Newton iterations.

Description

Type commandQueryIterations() to list the number of Newton iterations per continuation step in fort.9.
Type commandQueryIterations(‘xxx’) to list the number of Newton iterations per continuation step in the info file ’d.xxx’.

Aliases

iterations it
4.13.27  commandQueryLimitpoint

Purpose

Print the value of the “limit point function”.

Description

Type commandQueryLimitpoint() to list the value of the “limit point function” in the output-file fort.9. This function vanishes at a limit point (fold).
Type commandQueryLimitpoint('xxx') to list the value of the “limit point function” in the info file 'd.xxx'.

Aliases

lm limitpoint

4.13.28  commandQueryNote

Purpose

Print notes in info file.

Description

Type commandQueryNote() to show any notes in the output-file fort.9.
Type commandQueryNote('xxx') to show any notes in the info file 'd.xxx'.

Aliases

nt note
4.13.29 commandQuerySecondaryPeriod

Purpose
Print value of “secondary-periodic bif. fcn”.

Description
Type commandQuerySecondaryPeriod() to list the value of the “secondary-periodic bifurcation function” in the output-file 'fort.9. This function vanishes at period-doubling and torus bifurcations.
Type commandQuerySecondaryPeriod('xxx') to list the value of the “secondary-periodic bifurcation function” in the info file 'd.xxx'.

Aliases
sc secondaryperiod sp

4.13.30 commandQueryStepsize

Purpose
Print continuation step sizes.

Description
Type commandQueryStepsize() to list the continuation step size for each continuation step in 'fort.9.
Type commandQueryStepsize('xxx') to list the continuation step size for each continuation step in the info file 'd.xxx'.

Aliases
ss stepsize st
4.13.31 commandRun

Purpose

Run AUTO.

Description

Type commandRun([options]) to run AUTO with the given options. There are four possible options:

<table>
<thead>
<tr>
<th>Long name</th>
<th>Short name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>equation</td>
<td>e</td>
<td>The equations file</td>
</tr>
<tr>
<td>constants</td>
<td>c</td>
<td>The AUTO constants file</td>
</tr>
<tr>
<td>solution</td>
<td>s</td>
<td>The restart solution file</td>
</tr>
<tr>
<td>homcont</td>
<td>h</td>
<td>The Homcont parameter file</td>
</tr>
</tbody>
</table>

Options which are not explicitly set retain their previous value. For example one may type: commandRun(e='ab',c='ab.1') to use 'ab.c' as the equations file and c.ab.1 as the constants file (if you are using the default filename templates).

Type commandRun('name') load all files with base 'name'. This does the same thing as running commandRun(e='name',c='name',s='name',h='name').

Aliases

r run rn

4.13.32 commandRunnerConfigFort2

Purpose

Modify continuation constants.

Description

Type commandRunnerConfigFort2('xxx',yyy) to change the constant 'xxx' to have value yyy.

Aliases

changeconstant cc ch
4.13.33 commandRunnerLoadName

Purpose

Load files into the AUTO runner.

Description

Type commandRunnerLoadName([options]) to modify AUTO runner. There are four possible options:

<table>
<thead>
<tr>
<th>Long name</th>
<th>Short name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>equation</td>
<td>e</td>
<td>The equations file</td>
</tr>
<tr>
<td>constants</td>
<td>c</td>
<td>The AUTO constants file</td>
</tr>
<tr>
<td>solution</td>
<td>s</td>
<td>The restart solution file</td>
</tr>
<tr>
<td>homcont</td>
<td>h</td>
<td>The Homcont parameter file</td>
</tr>
</tbody>
</table>

Options which are not explicitly set retain their previous value. For example one may type: commandRunnerLoadName(e='ab',c='ab.1') to use ‘ab.c’ as the equations file and c.ab.1 as the constants file (if you are using the default filename templates).

Type commandRunnerLoadName('name') load all files with base ‘name’. This does the same thing as running commandRunnerLoadName(e='name',c='name,s='name',h='name').

Aliases

ld load
4.13.34  commandRunnerPrintFort2

Purpose
Print continuation parameters.

Description
Type commandRunnerPrintFort2() to print all the parameters. Type commandRunnerPrintFort2(‘xxx’) to return the parameter ‘xxx’.

Aliases
pc pr printconstant

4.13.35  commandShell

Purpose
Run a shell command.

Description
Type ’shell xxx’ to run the command ’xxx’ in the Unix shell and display the results in the AUTO command line user interface.

Aliases
shell
4.13.36 commandTriple

Purpose
Triple a solution.

Description
Type commandTriple() to triple the solution in 'fort.7' and 'fort.8'.
Type commandTriple('xxx') to triple the solution in b.xxx and s.xxx (if you are using
the default filename templates).

Aliases
tr triple

4.13.37 commandUserData

Purpose
Covert user-supplied data files.

Description
Type commandUserData('xxx') to convert a user-supplied data file 'xxx.dat' to
AUTO format. The converted file is called 's.dat'. The original file is left unchanged.
AUTO automatically sets the period in PAR(10). Other parameter values must be set
in 'stptnt'. (When necessary, PAR(10) may also be redefined there.) The constants-
file file 'c.xxx' must be present, as the AUTO-constants 'NTST' and 'NCOL' are used
to define the new mesh. For examples of using the 'userData' command see demos
'lor' and 'pen' (where it has the old name 'fc').

Aliases
us userdata
4.13.38 commandWait

Purpose

Wait for the user to enter a key.

Description

Type 'commandWait' to have the AUTO interface wait until the user hits any key (mainly used in scripts).

Aliases

wait
Chapter 5

Description of AUTO -Constants.

5.1 The AUTO -Constants File.

As described in Section 3.1, if the equations-file is \texttt{xxx.c} then the constants that define the computation are normally expected in the file \texttt{c.xxx}. The general format of this file is the same for all AUTO runs. For example, the file \texttt{c.ab} in directory \texttt{auto/2000/demos/ab} is listed below. (The tutorial demo \texttt{ab} is described in detail in Chapter 7.)

\begin{verbatim}
2 1 0 1 NDIM,IPS,IRS,ILP
1 1 NACP,(ICP(I),I=1,NACP)
50 4 3 1 1 0 0 0 NTST,NCOL,IAD,ISP,ISW,IPLT,NBC,NINT
100 0. 0.15 0. 100. NMX,RL0,RL1,A0,A1
100 10 2 8 5 3 0 NPR,MXBF,IID,ITMX,NWTN,JAC
1.e-6 1.e-6 0.0001 EPSL,EPSU,EPSS
0.01 0.005 0.05 1 DS,DSMIN,DSMAX,IADS
1 1 NTHL,((I,THL(I)),I=1,NTHL)
11 0.
0 NTHU,((I,THU(I)),I=1,NTHU)
0 NUZR,((I,UZR(I)),I=1,NUZR)
\end{verbatim}

The significance of the AUTO -constants, grouped by function, is described in the sections below. Representative demos that illustrate use of the AUTO -constants are also mentioned.

5.2 Problem Constants.

5.2.1 NDIM

Dimension of the system of equations as specified in the user-supplied subroutine \texttt{func}.

5.2.2 NBC

The number of boundary conditions as specified in the user-supplied subroutine \texttt{bcnd}. (Demos \texttt{exp, kar}.)

62
5.2.3  NINT
The number of integral conditions as specified in the user-supplied subroutine \texttt{icnd}.
(Demos int, lin, obv.)

5.2.4  JAC
Used to indicate whether derivatives are supplied by the user or to be obtained by differencing:

- JAC=0 : No derivatives are given by the user. (Most demos use JAC=0.)

- JAC=1 : Derivatives with respect to state- and problem-parameters are given in the user-supplied subroutines \texttt{func}, \texttt{bcnd}, \texttt{icnd} and \texttt{fopt}, where applicable. This may be necessary for sensitive problems. It is also recommended for computations in which AUTO generates an extended system, for example, when ISW=2.
(Demos int, dd2, obt, plp, ops.)
(For ISW see Section 5.8.3.)

5.3  Discretization Constants.

5.3.1  NTST
The number of mesh intervals used for discretization. NTST remains fixed during any particular run, but can be changed when restarting. Recommended value of NTST: As small as possible to maintain convergence.
(Demos exp, ab, spb.)
(For mesh adaption see IAD in Section 5.3.3.)

5.3.2  NCOL
The number of Gauss collocation points per mesh interval, (2 \leq NCOL \leq 7). NCOL remains fixed during any given run, but can be changed when restarting at a previously computed solution. The choice NCOL=4, used in most demos, is recommended. If NDIM is “large” and the solutions “very smooth” then NCOL=2 may be appropriate.

5.3.3  IAD
This constant controls the mesh adaption:

- IAD=0 : Fixed mesh. Normally, this choice should never be used, as it may result in spurious solutions. (Demo ext.)

- IAD>0 : Adapt the mesh every IAD steps along the branch. Most demos use IAD=3, which is the strongly recommended value.
When computing “trivial” solutions to a boundary value problem, for example, when all solution components are constant, then the mesh adaption may fail under certain circumstances, and overflow may occur. In such case, try recomputing the solution branch with a fixed mesh (IAD=0). Be sure to set IAD back to IAD=3 for computing eventual non-trivial bifurcating solution branches.

5.4 Tolerances.

5.4.1 EPSL
Relative convergence criterion for equation parameters in the Newton/Chord method. Most demos use EPSL=10^{-6} or EPSL=10^{-7}, which is the recommended value range.

5.4.2 EPSU
Relative convergence criterion for solution components in the Newton/Chord method. Most demos use EPSU=10^{-6} or EPSU=10^{-7}, which is the recommended value range.

5.4.3 EPSS
Relative arclength convergence criterion for the detection of special solutions. Most demos use EPSS=10^{-4} or EPSS=10^{-5}, which is the recommended value range. Generally, EPSS should be approximately 100 to 1000 times the value of EPSL, EPSU.

5.4.4 ITMX
The maximum number of iterations allowed in the accurate location of special solutions, such as bifurcations, folds, and user output points, by Müller’s method with bracketing. The recommended value is ITMX=8, used in most demos.

5.4.5 NWTN
After NWTN Newton iterations the Jacobian is frozen, i.e., AUTO uses full Newton for the first NWTN iterations and the Chord method for iterations NWTN+1 to ITNW. The choice NWTN=3 is strongly recommended and used in most demos. Note that this constant is only effective for ODEs, i.e., for solving the piecewise polynomial collocation equations. For algebraic systems AUTO always uses full Newton.

5.4.6 ITNW
The maximum number of combined Newton-Chord iterations. When this maximum is reached, the step will be retried with half the stepsize. This is repeated until convergence, or until the minimum stepsize is reached. In the latter case the computation of the branch is discontinued and a message printed in fort.9. The recommended value is ITNW=5, but ITNW=7 may be used for “difficult” problems, for example, demos spb, chu, plp, etc.
5.5 Continuation Step Size.

5.5.1 DS

AUTO uses pseudo-arclength continuation for following solution branches. The pseudo-arclength stepsize is the distance between the current solution and the next solution on a branch. By default, this distance includes all state variables (or state functions) and all free parameters. The constant DS defines the pseudo-arclength stepsize to be used for the first attempted step along any branch. (Note that if IADS>0 then DS will automatically be adapted for subsequent steps and for failed steps.) DS may be chosen positive or negative; changing its sign reverses the direction of computation. The relation DDMIN ≤ |DS| ≤ DMAX must be satisfied. The precise choice of DS is problem-dependent; the demos use a value that was found appropriate after some experimentation.

5.5.2 DDMIN

This is minimum allowable absolute value of the pseudo-arclength stepsize. DDMIN must be positive. It is only effective if the pseudo-arclength step is adaptive, i.e., if IADS>0. The choice of DDMIN is highly problem-dependent; most demos use a value that was found appropriate after some experimentation. See also the discussion in Section 6.2.

5.5.3 DMAX

The maximum allowable absolute value of the pseudo-arclength stepsize. DMAX must be positive. It is only effective if the pseudo-arclength step is adaptive, i.e., if IADS>0. The choice of DMAX is highly problem-dependent; most demos use a value that was found appropriate after some experimentation. See also the discussion in Section 6.2.

5.5.4 IADS

This constant controls the frequency of adaption of the pseudo-arclength stepsize.

- IADS=0 : Use fixed pseudo-arclength stepsize, i.e., the stepsize will be equal to the specified value of DS for every step. The computation of a branch will be discontinued as soon as the maximum number of iterations ITNW is reached. This choice is not recommended. (Demo tim.)

- IADS>0 : Adapt the pseudo-arclength stepsize after every IADS steps. If the Newton/Chord iteration converges rapidly then |DS| will be increased, but never beyond DMAX. If a step fails then it will be retried with half the stepsize. This will be done repeatedly until the step is successful or until |DS| reaches DMIN. In the latter case non-convergence will be signalled. The strongly recommended value is IADS=1, which is used in almost all demos.
5.5.5 NTHL

By default, the pseudo-arclength stepsize includes all state variables (or state functions) and all free parameters. Under certain circumstances one may want to modify the weight accorded to individual parameters in the definition of stepsize. For this purpose, NTHL defines the number of parameters whose weight is to be modified. If NTHL=0 then all weights will have default value 1.0. If NTHL>0 then one must enter NTHL pairs, Parameter Index Weight, with each pair on a separate line.

For example, for the computation of periodic solutions it is recommended that the period not be included in the pseudo-arclength continuation stepsize, in order to avoid period-induced limitations on the stepsize near orbits of infinite period. This exclusion can be accomplished by setting NTHL=1, with, on a separate line, the pair 11 0.0. Most demos that compute periodic solutions use this option; see for example demo ab.

5.5.6 NTHU

Under certain circumstances one may want to modify the weight accorded to individual state variables (or state functions) in the definition of stepsize. For this purpose, NTHU defines the number of states whose weight is to be modified. If NTHU=0 then all weights will have default value 1.0. If NTHU>0 then one must enter NTHU pairs, State Index Weight, with each pair on a separate line. At present none of the demos use this option.

5.6 Diagram Limits.

There are three ways to limit the computation of a branch:

- By appropriate choice of the computational window defined by the constants RL0, RL1, A0, and A1. One should always check that the starting solution lies within this computational window, otherwise the computation will stop immediately at the starting point.

- By specifying the maximum number of steps, NMX.

- By specifying a negative parameter index in the list associated with the constant NUZR; see Section 5.9.4.

5.6.1 NMX

The maximum number of steps to be taken along any branch.

5.6.2 RL0

The lower bound on the principal continuation parameter. (This is the parameter which appears first in the ICP list; see Section 5.7.1.).
5.6.3 RL1
The upper bound on the principal continuation parameter.

5.6.4 A0
The lower bound on the principal solution measure. (By default, if IPLT=0, the principal solution measure is the $L_2$-norm of the state vector or state vector function. See the AUTO -constant IPLT in Section 5.9.3 for choosing another principal solution measure.)

5.6.5 A1
The upper bound on the principal solution measure.

5.7 Free Parameters.

5.7.1 NICP, ICP
For each equation type and for each continuation calculation there is a typical (“generic”) number of problem parameters that must be allowed to vary, in order for the calculations to be properly posed. The constant NICP indicates how many free parameters have been specified, while the array ICP actually designates these free parameters. The parameter that appears first in the ICP list is called the “principal continuation parameter”. Specific examples and special cases are described below.

5.7.2 Fixed points.
The simplest case is the continuation of a solution branch to the system $f(u,p) = 0$, where $f(\cdot, \cdot), u \in \mathbb{R}^n$, cf. Equation (2.1). Such a system arises in the continuation of ODE stationary solutions and in the continuation of fixed points of discrete dynamical systems. There is only one free parameter here, so NICP=1.

As a concrete example, consider Run 1 of demo ab, where NICP=1, with ICP(1)=1. Thus, in this run PAR(1) is designated as the free parameter.

5.7.3 Periodic solutions and rotations.
The continuation of periodic solutions and rotations generically requires two parameters, namely, one problem parameter and the period. Thus, in this case NICP=2. For example, in Run 2 of demo ab we have NICP=2, with ICP(1)=1 and ICP(2)=11. Thus, in this run, the free parameters are PAR(1) and PAR(10). (Note that AUTO reserves PAR(10) for the period, or PAR(11) if you use a Fortran equations-file.)

Actually, for periodic solutions, one can set NICP=1 and only specify the index of the free problem parameter, as AUTO will automatically add the parameter with the period (10 or 11). However, in this case the period will not appear in the screen output and in the fort.7 output-file.
For fixed period orbits one must set \( \text{NICP}=2 \) and specify two free problem parameters. For example, in Run 7 of demo \texttt{pp2}, we have \( \text{NICP}=2 \), with \texttt{PAR(1)} and \texttt{PAR(2)} specified as free problem parameters. The period is fixed in this run. If the period is large then such a continuation provides a simple and effective method for computing a locus of homoclinic orbits.

### 5.7.4 Folds and Hopf bifurcations.

The continuation of folds for algebraic problems and the continuation of Hopf bifurcations requires two free problem parameters, i.e., \( \text{NICP}=2 \). For example, to continue a fold in Run 3 of demo \texttt{ab}, we have \( \text{NICP}=2 \), with \texttt{PAR(1)} and \texttt{PAR(3)} specified as free parameters. Note that one must set \( \text{ISW}=2 \) for computing such loci of special solutions. Also note that in the continuation of folds the principal continuation parameter must be the one with respect to which the fold was located.

### 5.7.5 Folds and period-doublings.

The continuation of folds, for periodic orbits and rotations, and the continuation of period-doubling bifurcations require two free problem parameters plus the free period. Thus, one would normally set \( \text{NICP}=3 \). For example, in Run 6 of demo \texttt{pen}, where a locus of period-doubling bifurcations is computed for rotations, we have \( \text{NICP}=3 \), with \texttt{PAR(2)}, \texttt{PAR(3)}, and the period specified as free parameters. Note that one must set \( \text{ISW}=2 \) for computing such loci of special solutions. Also note that in the continuation of folds the principal continuation parameter must be the one with respect to which the fold was located.

Actually, one may set \( \text{NICP}=2 \), and only specify the problem parameters, as AUTO will automatically add the period. For example, in Run 3 of demo \texttt{plp}, where a locus of folds is computed for periodic orbits, we have \( \text{NICP}=2 \), with \texttt{PAR(4)} and \texttt{PAR(1)} specified as free parameters. However, in this case the period will not appear in the screen output and in the \texttt{fort.7} output-file.

To continue a locus of folds or period-doublings with fixed period, simply set \( \text{NICP}=3 \) and specify three problem parameters, not including the period.

### 5.7.6 Boundary value problems.

The simplest case is that of boundary value problems where \( \text{NDIM}=\text{NBC} \) and where \( \text{NINT}=0 \). Then, generically, one free problem parameter is required for computing a solution branch. For example, in demo \texttt{exp}, we have \( \text{NDIM}=\text{NBC}=2, \text{NINT}=0 \). Thus \( \text{NICP}=1 \). Indeed, in this demo one free parameter is designated, namely \( \text{PAR(1)} \).

More generally, for boundary value problems with integral constraints, the generic number of free parameters is \( \text{NBC} + \text{NINT} - \text{NDIM} + 1 \). For example, in demo \texttt{lin}, we have \( \text{NDIM}=2, \text{NBC}=2, \text{NINT}=1 \). Thus \( \text{NICP}=2 \). Indeed, in this demo two free parameters are designated, namely \( \text{PAR(1)} \) and \( \text{PAR(3)} \).
5.7.7 Boundary value folds.

To continue a locus of folds for a general boundary value problem with integral constraints, set \( \text{NICP} = \text{NBC} + \text{NINT} - \text{NDIM} + 2 \), and specify this number of parameter indices to designate the free parameters.

5.7.8 Optimization problems.

In algebraic optimization problems one must set \( \text{ICP}(1)=9 \), as AUTO uses \( \text{PAR}(9) \) as principal continuation parameter to monitor the value of the objective function. Furthermore, one must designate one free equation parameter in \( \text{ICP}(2) \). Thus, \( \text{NICP}=2 \) in the first run.

Folds with respect to \( \text{PAR}(9) \) correspond to extrema of the objective function. In a second run one can restart at such a fold, with an additional free equation parameter specified in \( \text{ICP}(3) \). Thus, \( \text{NICP}=3 \) in the second run.

The above procedure can be repeated. For example, folds from the second run can be continued in a third run with three equation parameters specified in addition to \( \text{PAR}(9) \). Thus, \( \text{NICP}=4 \) in the third run.

For a simple example see demo \text{opt}, where a four-parameter extremum is located. Note that \( \text{NICP}=5 \) in each of the four constants-files of this demo, with the indices of \( \text{PAR}(9) \) and \( \text{PAR}(1)-\text{PAR}(4) \) specified in \( \text{ICP} \). Thus, in the first three runs, there are overspecified parameters. However, AUTO will always use the correct number of parameters. Although the overspecified parameters will be printed, their values will remain fixed.

5.7.9 Internal free parameters.

The actual continuation scheme in AUTO may use additional free parameters that are automatically added. The simplest example is the computation of periodic solutions and rotations, where AUTO automatically adds the period, if not specified. The computation of loci of folds, Hopf bifurcations, and period-doublings also requires additional internal continuation parameters. These will be automatically added, and their indices will be greater than 10.

5.7.10 Parameter overspecification.

The number of specified parameter indices is allowed to be greater than the generic number. In such case there will be “overspecified” parameters, whose values will appear in the screen and \text{fort.7} output, but which are not part of the continuation process. A simple example is provided by demo \text{opt}, where the first three runs have overspecified parameters whose values, although constant, are printed.

There is, however, a more useful application of parameter overspecification. In the user-supplied subroutine \text{pvl} one can define solution measures and assign these to otherwise unused parameters. Such parameters can then be overspecified, in order to print them on the screen and in the \text{fort.7} output. It is important to note that such overspecified parameters must appear at the end of the \( \text{ICP} \) list, as they cannot be used as true continuation parameters.

For an example of using parameter overspecification for printing user-defined solution measures, see demo \text{pvl}. This is a boundary value problem (Bratu’s equation) which has only one
true continuation parameter, namely \texttt{PAR(1)}. Three solution measures are defined in the subroutine \texttt{pvls}, namely, the $L_2$-norm of the first solution component, the minimum of the second component, and the left boundary value of the second component. These solution measures are assigned to \texttt{PAR(2)}, \texttt{PAR(3)}, and \texttt{PAR(4)}, respectively. In the constants-file \texttt{c.pvl} we have \texttt{NICP=4}, with \texttt{PAR(1)}-\texttt{PAR(4)} specified as parameters. Thus, in this example, \texttt{PAR(2)}-\texttt{PAR(4)} are overspecified. Note that \texttt{PAR(1)} must appear first in the \texttt{ICP} list; the other parameters cannot be used as true continuation parameters.

5.8 Computation Constants.

5.8.1 ILP

- \texttt{ILP=0} : No detection of folds. This choice is recommended.
- \texttt{ILP=1} : Detection of folds. To be used if subsequent fold continuation is intended.

5.8.2 ISP

This constant controls the detection of branch points, period-doubling bifurcations, and torus bifurcations.

- \texttt{ISP=0} : This setting disables the detection of branch points, period-doubling bifurcations, and torus bifurcations and the computation of Floquet multipliers.
- \texttt{ISP=1} : Branch points are detected for algebraic equations, but not for periodic solutions and boundary value problems. Period-doubling bifurcations and torus bifurcations are not located either. However, Floquet multipliers are computed.
- \texttt{ISP=2} : This setting enables the detection of all special solutions. For periodic solutions and rotations, the choice \texttt{ISP=2} should be used with care, due to potential inaccuracy in the computation of the linearized Poincaré map and possible rapid variation of the Floquet multipliers. The linearized Poincaré map always has a multiplier $z = 1$. If this multiplier becomes inaccurate then the automatic detection of secondary periodic bifurcations will be discontinued and a warning message will be printed in \texttt{fort.9}. See also Section 6.4.
- \texttt{ISP=3} : Branch points will be detected, but AUTO will not monitor the Floquet multipliers. Period-doubling and torus bifurcations will go undetected. This option is useful for certain problems with non-generic Floquet behavior. The Floquet multipliers will be output to the diagnostic file.

5.8.3 ISW

This constant controls branch switching at branch points for the case of differential equations. Note that branch switching is automatic for algebraic equations.
- **ISW=1**: This is the normal value of ISW.

- **ISW=−1**: If IRS is the label of a branch point or a period-doubling bifurcation then branch switching will be done. For period doubling bifurcations it is recommended that NTST be increased. For examples see Run 2 and Run 3 of demo lor, where branch switching is done at period-doubling bifurcations, and Run 2 and Run 3 of demo bvp, where branch switching is done at a transcritical branch point.

- **ISW=2**: If IRS is the label of a fold, a Hopf bifurcation point, or a period-doubling or torus bifurcation then a locus of such points will be computed. An additional free parameter must be specified for such continuations; see also Section 5.7.

### 5.8.4 MXBF

This constant, which is effective for algebraic problems only, sets the maximum number of bifurcations to be treated. Additional branch points will be noted, but the corresponding bifurcating branches will not be computed. If MXBF is positive then the bifurcating branches of the first MXBF branch points will be traced out in both directions. If MXBF is negative then the bifurcating branches of the first |MXBF| branch points will be traced out in only one direction.

### 5.8.5 IRS

This constant sets the label of the solution where the computation is to be restarted.

- **IRS=0**: This setting is typically used in the first run of a new problem. In this case a starting solution must be defined in the user-supplied subroutine stpnt; see also Section 3.3. For representative examples of analytical starting solutions see demos ab and frc. For starting from unlabeled numerical data see the @fc command (Section A) and demos lor and pen.

- **IRS>0**: Restart the computation at the previously computed solution with label IRS. This solution is normally expected to be in the current data-file q.xxx; see also the @r and @R commands in Section A. Various AUTO -constants can be modified when restarting.

### 5.8.6 IPS

This constant defines the problem type:

- **IPS=0**: An algebraic bifurcation problem. Hopf bifurcations will not be detected and stability properties will not be indicated in the fort.7 output-file.

- **IPS=1**: Stationary solutions of ODEs with detection of Hopf bifurcations. The sign of PT, the point number, in fort.7 is used to indicate stability: − is stable, + is unstable. (Demo ab.)

- **IPS=−1**: Fixed points of the discrete dynamical system \( u^{(k+1)} = f(u^{(k)}, p) \), with detection of Hopf bifurcations. The sign of PT in fort.7 indicates stability: − is stable, + is unstable. (Demo dd2.)
- **IPS=−2**: Time integration using implicit Euler. The AUTO -constants DS, DDMIN, DSMAX, and ITNW, NWTN control the stepsize. In fact, pseudo-arclength is used for “continuation in time”. Note that the time discretization is only first order accurate, so that results should be carefully interpreted. Indeed, this option has been included primarily for the detection of stationary solutions, which can then be entered in the user-supplied subroutine stpnt. (Demo ivp.)

- **IPS=2**: Computation of periodic solutions. Starting data can be a Hopf bifurcation point (Run 2 of demo ab), a periodic orbit from a previous run (Run 4 of demo pp2), an analytically known periodic orbit (Run 1 of demo frc), or a numerically known periodic orbit (Demo lor). The sign of PT in fort.7 is used to indicate stability: − is stable, + is unstable or unknown.

- **IPS=4**: A boundary value problem. Boundary conditions must be specified in the user-supplied subroutine bcnd and integral constraints in icnd. The AUTO -constants NBC and NINT must be given correct values. (Demos exp, int, kar.)

- **IPS=5**: Algebraic optimization problems. The objective function must be specified in the user-supplied subroutine fopt. (Demo opt.)

- **IPS=7**: A boundary value problem with computation of Floquet multipliers. This is a very special option; for most boundary value problems one should use IPS=4. Boundary conditions must be specified in the user-supplied subroutine bcnd and integral constraints in icnd. The AUTO -constants NBC and NINT must be given correct values.

- **IPS=9**: This option is used in connection with the HomCont algorithms described in Chapters 15-21 for the detection and continuation of homoclinic bifurcations. (Demos san, mtn, kpr, cir, she, rev.)

- **IPS=11**: Spatially uniform solutions of a system of parabolic PDEs, with detection of traveling wave bifurcations. The user need only define the nonlinearity (in subroutine func), initialize the wave speed in PAR(10), initialize the diffusion constants in PAR(15,16,…), and set a free equation parameter in ICP(1). (Run 2 of demo wav.)

- **IPS=12**: Continuation of traveling wave solutions to a system of parabolic PDEs. Starting data can be a Hopf bifurcation point from a previous run with IPS=11, or a traveling wave from a previous run with IPS=12. (Run 3 and Run 4 of demo wav.)

- **IPS=14**: Time evolution for a system of parabolic PDEs subject to periodic boundary conditions. Starting data may be solutions from a previous run with IPS=12 or 14. Starting data can also be specified in stpnt, in which case the wave length must be specified in PAR(10), and the diffusion constants in PAR(14,15,…). AUTO uses PAR(13) for the time variable. DS, DDMIN, and DSMAX govern the pseudo-arclength continuation in the space-time variables. Note that the time discretization is only first order accurate, so that results should be carefully interpreted. Indeed, this option is mainly intended for the detection of stationary waves. (Run 5 of demo wav.)
- **IPS=15**: Optimization of periodic solutions. The integrand of the objective functional must be specified in the user-supplied subroutine *fopt*. Only PAR(1–9) should be used for problem parameters. PAR(9) is the value of the objective functional, PAR(10) the period, PAR(11) the norm of the adjoint variables, PAR(13) and PAR(14) are internal optimality variables. PAR(20–28) and PAR(30) are used to monitor the optimality functionals associated with the problem parameters and the period. Computations can be started at a solution computed with IPS=2 or IPS=15. For a detailed example see demo ops.

- **IPS=16**: This option is similar to IPS=14, except that the user supplies the boundary conditions. Thus this option can be used for time-integration of parabolic systems subject to user-defined boundary conditions. For examples see the first runs of demos *pd1*, *pd2*, and *bru*. Note that the space-derivatives of the initial conditions must also be supplied in the user-supplied subroutine *stpnt*. The initial conditions must satisfy the boundary conditions. This option is mainly intended for the detecting stationary solutions.

- **IPS=17**: This option can be used to continue stationary solutions of parabolic systems obtained from an evolution run with IPS=16. For examples see the second runs of demos *pd1* and *pd2*.

### 5.9 Output Control.

#### 5.9.1 NPR

This constant can be used to regularly write *fort.8* plotting and restart data. IF **NPR>0** then such output is written every **NPR** steps. IF **NPR=0** or if **NPR≥NMX** then no such output is written. Note that special solutions, such as branch points, folds, end points, etc., are always written in *fort.8*. Furthermore, one can specify parameter values where plotting and restart data is to be written; see Section 5.9.4. For these reasons, and to limit the output volume, it is recommended that **NPR** output be kept to a minimum.

#### 5.9.2 IID

This constant controls the amount of diagnostic output printed in *fort.9*: the greater **IID** the more detailed the diagnostic output.

- **IID=0**: Minimal diagnostic output. This setting is not recommended.

- **IID=2**: Regular diagnostic output. This is the recommended value of **IID**.

- **IID=3**: This setting gives additional diagnostic output for algebraic equations, namely the Jacobian and the residual vector at the starting point. This information, which is printed at the beginning of *fort.9*, is useful for verifying whether the starting solution in *stpnt* is indeed a solution.

73
- **IID=4**: This setting gives additional diagnostic output for differential equations, namely the reduced system and the associated residual vector. This information is printed for every step and for every Newton iteration, and should normally be suppressed. In particular it can be used to verify whether the starting solution is indeed a solution. For this purpose, the stepsize DS should be small, and one should look at the residuals printed in the *fort.9* output-file. (Note that the first residual vector printed in *fort.9* may be identically zero, as it may correspond to the computation of the starting direction. Look at the second residual vector in such case.) This residual vector has dimension NDIM+ NBC+ NINT+1, which accounts for the NDIM differential equations, the NBC boundary conditions, the NINT user-defined integral constraints, and the pseudo-arclength equation. For proper interpretations of these data one may want to refer to the solution algorithm for solving the collocation system, as described in Doedel, Keller & Kernévez (1991b).

- **IID=5**: This setting gives very extensive diagnostic output for differential equations, namely, debug output from the linear equation solver. This setting should not normally be used as it may result in a huge *fort.9* file.

### 5.9.3 IPLT

This constant allows redefinition of the principal solution measure, which is printed as the second (real) column in the screen output and in the *fort.7* output-file:

- If IPLT = 0 then the $L_2$-norm is printed. Most demos use this setting. For algebraic problems, the standard definition of $L_2$-norm is used. For differential equations, the $L_2$-norm is defined as

$$\sqrt{\int_0^1 \sum_{k=1}^{NDIM} U_k(x)^2 \, dx}.$$  

Note that the interval of integration is $[0, 1]$, the standard interval used by AUTO. For periodic solutions the independent variable is transformed to range from 0 to 1, before the norm is computed. The AUTO-constants THL(*) and THU(*) (see Section 5.5.5 and Section 5.5.6) affect the definition of the $L_2$-norm.

- If $0 < \text{IPLT} \leq \text{NDIM}$ then the maximum of the IPLT’th solution component is printed.

- If $-\text{NDIM} \leq \text{IPLT} < 0$ then the minimum of the IPLT’th solution component is printed. (Demo fsh.)

- If $\text{NDIM} < \text{IPLT} \leq 2^*\text{NDIM}$ then the integral of the (IPLT− NDIM)’th solution component is printed. (Demos exp, lor.)

- If $2^*\text{NDIM} < \text{IPLT} \leq 3^*\text{NDIM}$ then the $L_2$-norm of the (IPLT− NDIM)’th solution component is printed. (Demo frc.)

Note that for algebraic problems the maximum and the minimum are identical. Also, for ODEs the maximum and the minimum of a solution component are generally much less accurate than the $L_2$-norm and component integrals. Note also that the subroutine *pvls* provides a second, more general way of defining solution measures; see Section 5.7.10.
5.9.4 NUZR

This constant allows the setting of parameter values at which labeled plotting and restart information is to be written in the fort.8 output-file. Optionally, it also allows the computation to terminate at such a point.

- Set NUZR=0 if no such output is needed. Many demos use this setting.

- If NUZR>0 then one must enter NUZR pairs, Parameter-Index Parameter-Value, with each pair on a separate line, to designate the parameters and the parameter values at which output is to be written. For examples see demos exp, int, and fsh.

- If such a parameter index is preceded by a minus sign then the computation will terminate at such a solution point. (Demos pen and bru.)

Note that fort.8 output can also be written at selected values of overspecified parameters. For an example see demo pvl. For details on overspecified parameters see Section 5.7.10.
Chapter 6

Notes on Using AUTO .

6.1 Restrictions on the Use of PAR.

The array PAR in the user-supplied subroutines is available for equation parameters that the user wants to vary at some point in the computations. In any particular computation the free parameter(s) must be designated in ICP; see Section 5.7. The following restrictions apply:

- The maximum number of parameters, NPARX in auto/2000/src/auto.c.h, has pre-defined value NPARX=36. NPARX should not normally be increased and it should never be decreased. Any increase of NPARX must be followed by recompilation of AUTO.

- Generally one should only use PAR(1)–PAR(9) for equation parameters, as AUTO may need the other components internally.

6.2 Efficiency.

In AUTO, efficiency has at times been sacrificed for generality of programming. This applies in particular to computations in which AUTO generates an extended system, for example, computations with ISW=2. However, the user has significant control over computational efficiency, in particular through judicious choice of the AUTO-constants DS, DSMIN, and DSMAX, and, for ODEs, NTST and NCOL. Initial experimentation normally suggests appropriate values.

Slowly varying solutions to ODEs can often be computed with remarkably small values of NTST and NCOL, for example, NTST=5, NCOL=2. Generally, however, it is recommended to set NCOL=4, and then to use the “smallest” value of NTST that maintains convergence.

The choice of the pseudo-arclength stepsize parameters DS, DSMIN, and DSMAX is highly problem dependent. Generally, DSMIN should not be taken too small, in order to prevent excessive step refinement in case of non-convergence. It should also not be too large, in order to avoid instant non-convergence. DSMAX should be sufficiently large, in order to reduce computation time and amount of output data. On the other hand, it should be sufficiently small, in order to prevent stepping over bifurcations without detecting them. For a given equation, appropriate values of these constants can normally be found after some initial experimentation.

The constants ITNW, WTN, THL, EPSU, EPSL, EPSS also affect efficiency. Understanding their significance is therefore useful; see Section 5.4 and Section 5.5. Finally, it is recommended
that initial computations be done with \( \text{ILP}=0 \); no fold detection; and \( \text{ISP}=1 \); no bifurcation detection for ODEs.

6.3 Correctness of Results.

AUTO-computed solutions to ODEs are almost always structurally correct, because the mesh adaption strategy, if \( \text{IAD}>0 \), safeguards to some extent against spurious solutions. If these do occur, possibly near infinite-period orbits, the unusual appearance of the solution branch typically serves as a warning. Repeating the computation with increased \( \text{NTST} \) is then recommended.

6.4 Bifurcation Points and Folds.

It is recommended that the detection of folds and bifurcation points be initially disabled. For example, if an equation has a “vertical” solution branch then AUTO may try to locate one fold after another.

Generally, degenerate bifurcations cannot be detected. Furthermore, bifurcations that are close to each other may not be noticed when the pseudo-arclength step size is not sufficiently small. Hopf bifurcation points may go unnoticed if no clear crossing of the imaginary axis takes place. This may happen when there are other real or complex eigenvalues near the imaginary axis and when the pseudo-arclength step is large compared to the rate of change of the critical eigenvalue pair. A typical case is a Hopf bifurcation close to a fold. Similarly, Hopf bifurcations may go undetected if switching from real to complex conjugate, followed by crossing of the imaginary axis, occurs rapidly with respect to the pseudo-arclength step size. Secondary periodic bifurcations may not be detected for similar reasons. In case of doubt, carefully inspect the contents of the diagnostics file \( \text{fort.9} \).

6.5 Floquet Multipliers.

AUTO extracts an approximation to the linearized Poincaré map from the Jacobian of the linearized collocation system that arises in Newton’s method. This procedure is very efficient; the map is computed at negligible extra cost. The linear equations solver of AUTO is described in Doedel, Keller & Kernévez (1991b). The actual Floquet multiplier solver was written by Fairgrieve (1994). For a detailed description of the algorithm see Fairgrieve & Jepson (1991).

For periodic solutions, the exact linearized Poincaré map always has a multiplier \( z = 1 \). A good accuracy check is to inspect this multiplier in the diagnostics output-file \( \text{fort.9} \). If this multiplier becomes inaccurate then the automatic detection of potential secondary periodic bifurcations (if \( \text{ISP}=2 \)) is discontinued and a warning is printed in \( \text{fort.9} \). It is strongly recommended that the contents of this file be habitually inspected, in particular to verify whether solutions labeled as BP or TR (cf. Table 3.1) have indeed been correctly classified.
6.6 Memory Requirements.

Pre-defined maximum values of certain AUTO -constants are in `auto/2000/src/auto_c.h`; see also Section 1.3. These maxima affect the run-time memory requirements and should not be set to unnecessarily large values. If an application only solves algebraic systems and if `NDIM` is “large” then memory requirements can be much reduced by setting each of `NTSTX`, `NCOLX`, `NBCX`, `NINTX`, equal to 1 in `auto/2000/src/auto_c.h`, followed by recompilation of the AUTO libraries.
Chapter 7

AUTO Demos : Tutorial.
7.1 Introduction.

The directory auto/2000/demos has a large number of subdirectories, for example ab, pp2, exp, etc., each containing all necessary files for certain illustrative calculations. Each subdirectory, say xxx, corresponds to a particular equation and contains one equations-file xxx.c and one or more constants-files c.xxx.i, one for each successive run of the demo. To see how the equations have been programmed, inspect the equations-file. To understand in detail how AUTO is instructed to carry out a particular task, inspect the appropriate constants-file. In this chapter we describe the tutorial demo ab in detail. A brief description of other demos is given in later chapters.

7.2 ab : A Tutorial Demo.

This demo illustrates the computation of stationary solutions, Hopf bifurcations and periodic solutions, and the computation loci of folds and Hopf bifurcation points. The equations, that model an A → B reaction, are those from Uppal, Ray & Poore (1974), namely

\[ \begin{align*}
    u_1' &= -u_1 + p_1 (1 - u_1) e^{u_2}, \\
    u_2' &= -u_2 + p_1 p_2 (1 - u_1) e^{u_2} - p_3 u_2.
\end{align*} \]  

(7.1)

7.3 Copying the Demo Files.

The commands listed in Table 7.1 will copy the demo files to your work directory.

<table>
<thead>
<tr>
<th>Unix-COMMAND</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>start the AUTO2000 Command Line User Interface</td>
</tr>
<tr>
<td>AUTO -COMMAN</td>
<td>ACTION</td>
</tr>
<tr>
<td>cd</td>
<td>go to main directory (or other directory).</td>
</tr>
<tr>
<td>! mkdir ab</td>
<td>create an empty work directory. Note: the '!' is used to signify a command which is sent to the shell.</td>
</tr>
<tr>
<td>cd ab</td>
<td>change to the work directory.</td>
</tr>
<tr>
<td>demo('ab')</td>
<td>copy the demo files to the work directory.</td>
</tr>
</tbody>
</table>

Table 7.1: Copying the demo ab files.

At this point you may want to see what files have been copied to the work directory. In particular, you may want to edit the equations-file ab.c to see how the equations have been entered (in subroutine func) and how the starting solution has been set (in subroutine stpnt). Note that, initially, \( p_1 = 0 \), \( p_2 = 14 \), and \( p_3 = 2 \), for which \( u_1 = u_2 = 0 \) is a stationary solution.
7.4 Executing all Runs Automatically.

To execute all prepared runs of demo \texttt{ab}, simply type one or both of the command given in Table 7.2.

<table>
<thead>
<tr>
<th>AUTO -COMMAND</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>demofile(‘ab_old_auto’)</td>
<td>execute all runs of demo \texttt{ab} interactively using a new constants file for each run</td>
</tr>
<tr>
<td>demofile(‘ab_new_auto’)</td>
<td>execute all runs of demo \texttt{ab} interactively by modifying the constants file before each run</td>
</tr>
</tbody>
</table>

Table 7.2: Executing all runs of demo \texttt{ab}.

Each of the commands in Table 7.2 begins a tutorial which will proceed one step each time the user presses a key. Each step consists of a single AUTO command preceded by instructions as to what action the command performs. The tutorial script \texttt{ab\_old\_auto} performs the demo by reading in a sequence of AUTO constants files each of which corresponds to a step of the demo. The tutorial script \texttt{ab\_new\_auto} performs the demo by reading in a single AUTO constants file and then interactively modifying it to perform each of the demo. Both are valid and effective methods for running AUTO, with \texttt{ab\_old\_auto} being similar to the way AUTO was used before the advent of the CLUI, and \texttt{ab\_new\_auto} using new functionality provided by the CLUI.

Note that there are five separate runs. In the first run, a branch of stationary solutions is traced out. Along it, two folds (LP) and one Hopf bifurcation (HB) are located. The free parameter is \(p_1\). The other parameters remain fixed in this run. Note also that only special, labeled solution points are printed on the screen. More detailed results are saved in the data-files \texttt{b.ab}, \texttt{s.ab}, and \texttt{d.ab}.

The second run traces out the branch of periodic solutions that emanates from the Hopf bifurcation. The free parameters are \(p_1\) and the period. The detailed results are appended to the existing data-files \texttt{b.ab}, \texttt{s.ab}, and \texttt{d.ab}.

In the third run, one of the folds detected in the first run is followed in the two parameters \(p_1\) and \(p_3\), while \(p_2\) remains fixed. The fourth run continues this branch in opposite direction. Similarly, in the fifth run, the Hopf bifurcation located in the first run is followed in the two parameters \(p_1\) and \(p_3\). (In this example this is done in one direction only.) The detailed results of these continuations are accumulated in the data-files \texttt{b.2p}, \texttt{s.2p}, and \texttt{d.2p}.

The numerical results are given below in somewhat abbreviated form. Some differences in output are to be expected on different machines. This does not mean that the results have different accuracy, but simply that arithmetic differences have accumulated from step to step, possibly leading to different step size decisions.

One could now use the AUTO CLUI to graphically inspect the contents of the data-files, but we shall do this later. However, it may be useful to edit these files to view their contents.

Next, reset the work directory, by typing the command given in Table 7.3.
Table 7.3: Cleaning the demo ab work directory.

7.5 Executing Selected Runs Automatically.

As illustrated by the commands in Table 7.6, one can also execute selected runs of demo ab. In general, this cannot be done in arbitrary order, as any given run may need restart data from a previous run. Run 3 only requires the results of Run 1, so that the displayed command sequence is indeed appropriate. The screen output of these runs will be identical to that of the corresponding earlier runs, except for a change in solution labels in Run 3.

In real use there are two mains ways in which the AUTO can be used. First, one can prepare a constants-file for each run. In the illustrative runs below, the constants-files were carefully prepared in advance. For example, the file c.ab.1 contains the AUTO -constants for Run 1, c.ab.3 contains the AUTO -constants for Run 3, etc.

<table>
<thead>
<tr>
<th>AUTO -COMMAND</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ld(&quot;ab&quot;)</td>
<td>load the problem definition ab</td>
</tr>
<tr>
<td>run(c=&quot;ab.1&quot;)</td>
<td>execute the run which uses the constants in c.ab.1</td>
</tr>
<tr>
<td>sv(&quot;ab&quot;)</td>
<td>save the results of the run into the files b.ab, s.ab, and d.ab</td>
</tr>
<tr>
<td>run(c=&quot;ab.3&quot;,s=&quot;ab&quot;)</td>
<td>execute the third run of demo ab</td>
</tr>
</tbody>
</table>

Table 7.4: Selected runs of demo ab.

On the other hand, one can use the CLUI to generate the constants file at runtime. In the example below, the constant file c.ab.1 will be read in, and the CLUI will be used to make the appropriate changes to perform the same calculation as in Table 7.6.

<table>
<thead>
<tr>
<th>AUTO -COMMAND</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ld(&quot;ab&quot;)</td>
<td>load the problem definition ab</td>
</tr>
<tr>
<td>run(c=&quot;ab.1&quot;)</td>
<td>execute the run which uses the constants in c.ab.1</td>
</tr>
<tr>
<td>sv(&quot;ab&quot;)</td>
<td>save the results of the run into the files b.ab, s.ab, and d.ab</td>
</tr>
<tr>
<td>cc(&quot;IRS&quot;,2)</td>
<td>start the new calculation from a solution with label 2</td>
</tr>
<tr>
<td>cc(&quot;ICP&quot;,[1,3])</td>
<td>since we are following a locus of folds we require two free parameters</td>
</tr>
<tr>
<td>cc(&quot;ISP&quot;,0)</td>
<td>turn off detection of branch points</td>
</tr>
<tr>
<td>cc(&quot;ISW&quot;,2)</td>
<td>since we start at a fold the ISW parameter indicates we desire to compute a locus of such points</td>
</tr>
<tr>
<td>cc(&quot;DSMAX&quot;,0.5)</td>
<td>increase the maximum allowed step size</td>
</tr>
<tr>
<td>run(s=&quot;ab&quot;)</td>
<td>execute the third run of demo ab</td>
</tr>
</tbody>
</table>

Table 7.5: Selected runs of demo ab.

7.6 Using AUTO -Commands.

Next, with the commands in Table ??, we execute the first two runs of demo ab again, using commands similar Table ?? that one would normally use in an actual application. We still use
<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table 7.7: Differences in AUTO -constants between c.ab.1 and c.ab.2.

Actually, for periodic solutions, AUTO automatically adds PAR(10) (the period) as second parameter. However, for the period to be printed, one must specify the index 10 in the ICP list, as shown in Table 7.7.

7.7 Plotting the Results with AUTO .

The bifurcation diagram computed in the runs above is stored in the file b.ab, while each labeled solution is fully stored in s.ab. To use AUTO to graphically inspect these data-files, type the AUTO -command given in Table 7.8. The saved plots are shown in Figure 7.1 and in Figure 7.2.

Figure 7.1 shows the default view of the plotting tool, which consists of a representation of the bifurcation diagram. Step by step instructions for creating Figure 7.2 are given below.

The plotting window consists of a menubar at the top, a plotting area, and a control panel with four control widgets at the bottom. The first step in creating Figure 7.2 is to change the mode of the plotting tool from “bifurcation” to “solution”. This is accomplished by clicking on the widget marked “Type” on the bottom control panel and setting it from “bifurcation” to “solution”. In
the plotting window will appear a plot of the first labeled solution in \textit{s.ab}. Unfortunately, this is an equilibrium solution, so only a single point is plotted. Since we wish to plot the periodic solutions, we modify the widget marked “Label” by changing its value from “[1]” to “[6,7,10]” (don’t forget to hit the return key when you are done modifying the value). This signifies that instead of plotting the solution with label 1 we want to plot the solutions with labels 6, 7, and 10 simultaneously. In the plotting window we now have three curves, each of which is a plot of time versus the value of the first state variable. If we want a different plot, say the values of the two state variables plotted against each other, we use the two remaining widgets in the control panel, labeled “X” and “Y”. For example, if change the value of “X” from “[t]” to “[0]” and the value of “Y” from “[0]” to “[1]” we get a phase plot of the period solutions (don’t forget to hit the return key when you are done modifying each value). This plot is shown in Figure 7.2.

The plotting tool can also be used to create Postscript files from plots by selecting the “File” on the menubar and then selecting the “Save Postscript...” from the drop down menu. This will bring up a dialog into which the user can enter the filename of the postscript file to save the plot in. Further information on the plotting tool can be found in Section 4.10.

<table>

### 7.9 Relabeling Solutions in the Data-Files.

Next we want to plot the two-parameter diagram computed in the last three runs. However, the solution labels in these runs are not distinct. This is due to the fact that in each of these three runs the restart solution was read from \(s.ab\), while the computed solutions were stored in \(s.2p\). Consequently, these runs were unaware of each other’s results, which led to non-unique labels. For relabeling purpose, and more generally for file maintenance, there is a utility program that can be invoked as indicated in Table 7.10. Its use is illustrated in Table 7.11.

<table>
<thead>
<tr>
<th>AUTO - COMMAND</th>

Figure 7.3: Loci of folds and Hopf bifurcations for demo $ab$. 
Chapter 8

AUTO Demos: Fixed points.

8.1 enz: Stationary Solutions of an Enzyme Model.

The equations, that model a two-compartment enzyme system (Kernévez (1980)), are given by

\[
\begin{align*}
    s'_1 &= (s_0 - s_1) + (s_2 - s_1) - \rho R(s_1), \\
    s'_2 &= (s_0 + \mu - s_2) + (s_1 - s_2) - \rho R(s_2),
\end{align*}
\]

where

\[
R(s) = \frac{s}{1 + s + \kappa s^2}.
\]

The free parameter is \( s_0 \). Other parameters are fixed. This equation is also considered in Doedel, Keller & Kernévez (1991a).

<table>
<thead>
<tr>
<th>AUTO COMMAND</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>! mkdir enz</td>
<td>create an empty work directory</td>
</tr>
<tr>
<td>cd enz</td>
<td>change directory</td>
</tr>
<tr>

<td>save output-files as b.enz, s.enz, d.enz</td>
</tr>
</tbody>
</table>

Table 8.1: Commands for running demo enz.
8.2 dd2 : Fixed Points of a Discrete Dynamical System.

This demo illustrates the computation of a solution branch and its bifurcating branches for a discrete dynamical system. Also illustrated is the continuation of Naimark-Sacker (or Hopf) bifurcations. The equations, a discrete predator-prey system, are

\[
\begin{align*}
    u^{k+1}_1 &= p_1 u^k_1 (1 - u^k_1) - p_2 u^k_1 u^k_2, \\
    u^{k+1}_2 &= (1 - p_3) u^k_2 + p_2 u^k_1 u^k_2.
\end{align*}
\] (8.2)

In the first run, \(p_1\) is free. In the second run, both \(p_1\) and \(p_2\) are free. The remaining equation parameter, \(p_3\), is fixed in both runs.

<table>
<thead>
<tr>
<th>AUTO -COMMAND</th>
<th>ACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>! mkdir dd2</td>
<td>create an empty work directory</td>
</tr>
<tr>
<td>cd dd2</td>

</tbody>
</table>

Table 8.2: Commands for running demo dd2.
Chapter 9

AUTO Demos : Periodic solutions.
9.1 \textit{lrz : The Lorenz Equations.}

This demo computes two symmetric homoclinic orbits in the Lorenz equations

\begin{align*}
  u'_1 &= p_3(u_2 - u_1), \\
  u'_2 &= p_1u_1 - u_2 - u_1u_3, \\
  u'_3 &= u_1u_2 - p_2u_3.
\end{align*}

(9.1)

Here $p_1$ is the free parameter, and $p_2 = 8/3$, $p_3 = 10$. The two homoclinic orbits correspond to the final, large period orbits on the two periodic solution branches.

Table 9.3: Commands for running demo \textbf{pp2}.  

94
9.4 lor: Starting an Orbit from Numerical Data.

This demo illustrates how to start the computation of a branch of periodic solutions from numerical data obtained, for example, from an initial value solver. As an illustrative application we consider the Lorenz equations

\[
\begin{align*}
    u'_1 &= p_3(u_2 - u_1), \\
    u'_2 &= p_1u_1 - u_2 - u_1u_3, \\
    u'_3 &= u_1u_2 - p_2u_3.
\end{align*}
\]

(9.4)

Numerical simulations with a simple initial value solver show the existence of a stable periodic orbit when \( p_1 = 280, p_2 = 8/3, p_3 = 10 \). Numerical data representing one complete periodic oscillation are contained in the file lor.dat. Each row in lor.dat contains four real numbers, namely, the time variable \( t \), \( u_1 \), \( u_2 \) and \( u_3 \). The corresponding parameter values are defined in the user-supplied subroutine stpnt. The AUTO -command us(‘lor’) then converts the data in lor.dat to a labeled AUTO solution (with label 1) in a new file s.dat. The mesh will be suitably adapted to the solution, using the number of mesh intervals NTST and the number of collocation point per mesh interval NCOL specified in the constants-file c.lor. (Note that the file s.dat should be used for restart only. Do not append new output-files to s.dat, as the command us(‘lor’) only creates s.dat, with no corresponding b.dat.)

<table>
<thead>
<tr>
<th>AUTO -COMMAND</th>

9.5 \textbf{frc : A Periodically Forced System.}

This demo illustrates the computation of periodic solutions to a periodically forced system. In AUTO this can be done by adding a nonlinear oscillator with the desired periodic forcing as one of the solution components. An example of such an oscillator is

\begin{align}
x' &= x + \beta y - x(x^2 + y^2), \\
y' &= -\beta x + y - y(x^2 + y^2),
\end{align}

(9.5)

which has the asymptotically stable solution \( x = \sin(\beta t), y = \cos(\beta t) \). We couple this oscillator to the Fitzhugh-Nagumo equations:

\begin{align}
v' &= (F(v) - w)/\epsilon, \\
w' &= v - dw - (b + r \sin(\beta t)),
\end{align}

(9.6)

by replacing \( \sin(\beta t) \) by \( x \). Above, \( F(v) = v(v - a)(1 - v) \) and \( a, b, \epsilon \) and \( d \) are fixed. The first run is a homotopy from \( r = 0 \), where a solution is known analytically, to \( r = 0.2 \). Part of the solution branch with \( r = 0.2 \) and varying \( \beta \) is computed in the second run. For detailed results see Alexander, Doedel & Othmer (1990).

---

96
This demo illustrates the continuation of Hopf bifurcations in a 3-dimensional predator prey model (Doedel (1984)). This curve contain branch points, where one locus of Hopf points bifurcates from another locus of Hopf points. The equations are

\[
\begin{align*}
    u'_1 &= u_1(1 - u_1) - p_4 u_1 u_2, \\
    u'_2 &= -p_2 u_2 + p_4 u_1 u_2 - p_5 u_2 u_3 - p_1 (1 - e^{-p_6 u_2}), \\
    u'_3 &= -p_3 u_3 + p_5 u_2 u_3.
\end{align*}
\] (9.7)

Here \( p_2 = 1/4, p_3 = 1/2, p_4 = 3, p_5 = 3, p_6 = 5, \) and \( p_1 \) is the free parameter. In the continuation of Hopf points the parameter \( p_4 \) is also free.

9.7  **plp : Fold Continuation for Periodic Solutions.**

This demo, which corresponds to computations in Doedel, Keller & Kerner (1991a), shows how one can continue a fold on a branch of periodic solution in two parameters. The calculation of a locus of Hopf bifurcations is also included. The equations, that model a one-compartment activator-inhibitor system (Kerner (1980)), are given by

\[
s' = (s_0 - s) - \rho R(s, a), \\
a' = \alpha (a_0 - a) - \rho R(s, a),
\]

(9.8)

where

\[
R(s, a) = \frac{sa}{1 + s + \kappa s^2}, \quad \kappa > 0.
\]

The free parameter is \( \rho \). In the fold continuation \( s_0 \) is also free.

9.8 pp3 : Period-Doubling Continuation.

This demo illustrates the computation of stationary solutions, Hopf bifurcations, and periodic solutions, branch switching at a period-doubling bifurcation, and the computation of a locus of period-doubling bifurcations. The equations model a 3D predator-prey system with harvesting (Doedel (1984)).

\[
\begin{align*}
  u'_1 &= u_1(1 - u_1) - p_4 u_1 u_2, \\
  u'_2 &= -p_2 u_2 + p_4 u_1 u_2 - p_5 u_2 u_3 - p_1 (1 - e^{-p_6 u_2}), \\
  u'_3 &= -p_3 u_3 + p_5 u_2 u_3.
\end{align*}
\] (9.9)

The free parameter is \( p_1 \), except in the period-doubling continuation, where both \( p_1 \) and \( p_2 \) are free.

9.9 tor : Detection of Torus Bifurcations.

This demo uses a model in Freire, Rodríguez-Luis, Gamero & Ponce (1993) to illustrate the detection of a torus bifurcation. It also illustrates branch switching at a secondary periodic bifurcation with double Floquet multiplier at \( z = 1 \). The computational results also include folds, homoclinic orbits, and period-doubling bifurcations. Their continuation is not illustrated here; see instead the demos \( \text{plp, pp2, and pp3} \), respectively. The equations are

\[
\begin{align*}
x'(t) & = \left[-(\beta + \nu)x + \beta y - a_3 x^3 + b_3(y - x)^3\right]/r, \\
y'(t) & = \beta x - (\beta + \gamma)y - z - b_3(y - x)^3, \\
z'(t) & = y,
\end{align*}
\]

where \( \gamma = -0.6, r = 0.6, a_3 = 0.328578, \) and \( b_3 = 0.933578. \) Initially \( \nu = -0.9 \) and \( \beta = 0.5. \)

100
9.10   pen : Rotations of Coupled Pendula.

This demo illustrates the computation of rotations, i.e., solutions that are periodic, modulo a phase gain of an even multiple of $\pi$. AUTO checks the starting data for components with such a phase gain and, if present, it will automatically adjust the computations accordingly. The model equations, a system of two coupled pendula, (Doedel, Aronson & Othmer (1991)), are given by

\[
\begin{align*}
\phi_1'' + \epsilon \phi_1' + \sin \phi_1 &= I + \gamma (\phi_2 - \phi_1), \\
\phi_2'' + \epsilon \phi_2' + \sin \phi_2 &= I + \gamma (\phi_1 - \phi_2), 
\end{align*}
\]

or, in equivalent first order form,

\[
\begin{align*}
\phi_1' &= \psi_1, \\
\phi_2' &= \psi_2, \\
\psi_1' &= -\epsilon \psi_1 - \sin \phi_1 + I + \gamma (\phi_2 - \phi_1), \\
\psi_2' &= -\epsilon \psi_2 - \sin \phi_2 + I + \gamma (\phi_1 - \phi_2). 
\end{align*}
\]

Throughout $\gamma = 0.175$. Initially, $\epsilon = 0.1$ and $I = 0.4$.

Numerical data representing one complete rotation are contained in the file pen.dat. Each row in pen.dat contains five real numbers, namely, the time variable $t$, $\phi_1$, $\phi_2$, $\psi_1$ and $\psi_2$. The corresponding parameter values are defined in the user-supplied subroutine stpnt.

Actually, in this example, a scaled time variable $\tilde{t}$ is given in pen.dat. For this reason the period ( \PAR(11) ) is also set in stpnt. Normally AUTO would automatically set the period according to the data in pen.dat.

The AUTO -command us(‘pen’) converts the data in pen.dat to a labeled AUTO solution (with label 1) in a new file s.dat. The mesh will be suitably adapted to the solution, using the number of mesh intervals NTST and the number of collocation point per mesh interval NCOL specified in the constants-file c.pen. (Note that the file s.dat should be used for restart only. Do not append new output-files to s.dat, as the command us(‘pen’) only creates s.dat, with no corresponding b.dat.)

The first run, with $I$ as free problem parameter, starts from the converted solution with label 1 in pen.dat. A period-doubling bifurcation is located, and the period-doubled branch is computed in the second run. Two branch points are located, and the bifurcating branches are traced out in the third and fourth run, respectively. The fifth run generates starting data for the subsequent computation of a locus of period-doubling bifurcations. The actual computation is done in the sixth run, with $\epsilon$ and $I$ as free problem parameters.

Table 9.10: Commands for running demo pen.
9.11 chu : A Non-Smooth System (Chua’s Circuit).

Chua’s circuit is one of the simplest electronic devices to exhibit complex behavior. For related calculations see Khibnik, Roose & Chua (1993). The equations modeling the circuit are

\[
\begin{align*}
    u_1' &= \alpha \left[ u_2 - h(u_1) \right], \\
    u_2' &= u_1 - u_2 + u_3, \\
    u_3' &= -\beta u_2,
\end{align*}
\]  (9.13)

where

\[
h(x) = a_1 x + \frac{1}{2} \left( a_0 - a_1 \right) \left\{ | x + 1 | - | x - 1 | \right\},
\]

and where we take \( \beta = 14.3, a_0 = -1/7, a_1 = 2/7 \).

Note that \( h(x) \) is not a smooth function, and hence the solution to the equations may have non-smooth derivatives. However, for the orthogonal collocation method to attain its optimal accuracy, it is necessary that the solution be sufficiently smooth. Moreover, the adaptive mesh selection strategy will fail if the solution or one of its lower order derivatives has discontinuities. For these reasons we use the smooth approximation

\[
| x | \approx \frac{2x}{\pi} \arctan(Kx),
\]

which get better as \( K \) increases. In the numerical calculations below we use \( K = 10 \). The free parameter is \( \alpha \).

Table 9.11: Commands for running demo chu.

103
9.12  phs : Effect of the Phase Condition.

This demo illustrates the effect of the phase condition on the computation of periodic solutions. We consider the differential equation

\[
\begin{align*}
    u_1' &= \lambda u_1 - u_2, \\
    u_2' &= u_1(1 - u_1). \\
\end{align*}
\] (9.14)

This equation has a Hopf bifurcation from the trivial solution at \( \lambda = 0 \). The bifurcating branch of periodic solutions is vertical and along it the period increases monotonically. The branch terminates in a homoclinic orbit containing the saddle point \((u_1, u_2) = (1, 0)\). Graphical inspection of the computed periodic orbits, for example \( u_1 \) versus the scaled time variable \( t \), shows how the phase condition has the effect of keeping the “peak” in the solution in the same location.

Table 9.12: Commands for running demo phs.
9.13 ivp : Time Integration with Euler’s Method.

This demo uses Euler’s method to locate a stationary solution of the following predator-prey system with harvesting:

\[ \begin{align*}
    u'_1 &= p_2 u_1 (1 - u_1) - u_1 u_2 - p_1 (1 - e^{-p_3 u_1}), \\
    u'_2 &= -u_2 + p_4 u_1 u_2,
\end{align*} \tag{9.15} \]

where all problem parameters have a fixed value. The equations are the same as those in demo pp2. The continuation parameter is the independent time variable, namely PAR(14).

Note that Euler time integration is only first order accurate, so that the time step must be sufficiently small to ensure correct results. Indeed, this option has been added only as a convenience, and should generally be used only to locate stationary states. Note that the AUTO constants DS, DMIN, and DMAX control the step size in the space consisting of time, here PAR(14), and the state vector, here \((u_1, u_2)\).

Table 10.3: Commands for running demo **bvp**.
10.4 lin : A Linear ODE Eigenvalue Problem.

This demo illustrates the location of eigenvalues of a linear ODE boundary value problem as bifurcations from the trivial solution branch. By means of branch switching an eigenfunction is computed, as is illustrated for the first eigenvalue. This eigenvalue is then continued in two parameters by fixing the $L_2$-norm of the first solution component. The eigenvalue problem is given by the equations

\[
\begin{align*}
  u_1' &= u_2, \\
  u_2' &= (p_1 \pi)^2 u_1,
\end{align*}
\]  

(10.4)

with boundary conditions $u_1(0) - p_2 = 0$ and $u_1(1) = 0$. We add the integral constraint

\[
\int_0^1 u_1(t)^2 dt - p_3 = 0.
\]

Then $p_3$ is simply the $L_2$-norm of the first solution component. In the first two runs $p_2$ is fixed, while $p_1$ and $p_3$ are free. In the third run $p_3$ is fixed, while $p_1$ and $p_2$ are free.

Table 10.4: Commands for running demo lin.
10.5  non : A Non-Autonomous BVP.

This demo illustrates the continuation of solutions to the non-autonomous boundary value problem

\[
\begin{align*}
  u_1' &= u_2, \\
  u_2' &= -p_1 e^{x^3} u_1,
\end{align*}
\]  

(10.5)

with boundary conditions \( u_1(0) = 0, \quad u_1(1) = 0 \). Here \( x \) is the independent variable. This system is first converted to the following equivalent autonomous system:

\[
\begin{align*}
  u_1' &= u_2, \\
  u_2' &= -p_1 e^{u_3^2} u_1, \\
  u_3' &= 1,
\end{align*}
\]  

(10.6)

with boundary conditions \( u_1(0) = 0, \quad u_1(1) = 0, \quad u_3(0) = 0 \). (For a periodically forced system see demo frc).

</table>

Table 10.5: Commands for running demo non.
10.6 kar : The Von Karman Swirling Flows.

The steady axi-symmetric flow of a viscous incompressible fluid above an infinite rotating disk is modeled by the following ODE boundary value problem (Equation (11) in Lentini & Keller (1980):

\[
\begin{align*}
    u_1' &= Tu_2, \\
    u_2' &= Tu_3, \\
    u_3' &= Tu_4 + [u_2^2 - 2u_1u_3 - u_4^2]T, \\
    u_4' &= Tu_5, \\
    u_5' &= [2u_2u_4 - 2u_1u_5]T, \\
\end{align*}
\]

(10.7)

with left boundary conditions

\[ u_1(0) = 0, \quad u_2(0) = 0, \quad u_4(0) = 1 - \gamma, \]

and (asymptotic) right boundary conditions

\[
\begin{align*}
    \left[ f_{\infty} + a(f_{\infty}, \gamma) \right] u_2(1) + u_3(1) - \gamma \frac{u_4(1)}{a(f_{\infty}, \gamma)} &= 0, \\
    a(f_{\infty}, \gamma) \frac{b^2(f_{\infty}, \gamma)}{\gamma} u_2(1) + \left[ f_{\infty} + a(f_{\infty}, \gamma) \right] u_4(1) + u_5(1) &= 0, \\
    u_1(1) &= f_{\infty}, \\
\end{align*}
\]

(10.8)

where

\[
\begin{align*}
    a(f_{\infty}, \gamma) &= \frac{1}{\sqrt{2}} \left[ (f_{\infty}^4 + 4 \gamma^2)^{1/2} + f_{\infty}^2 \right]^{1/2}, \\
    b(f_{\infty}, \gamma) &= \frac{1}{\sqrt{2}} \left[ (f_{\infty}^4 + 4 \gamma^2)^{1/2} - f_{\infty}^2 \right]^{1/2}. \\
\end{align*}
\]

(10.9)

Note that there are five differential equations and six boundary conditions. Correspondingly, there are two free parameters in the computation of a solution branch, namely \( \gamma \) and \( f_{\infty} \). The “period” \( T \) is fixed; \( T = 500 \). The starting solution is \( u_i = 0, \ i = 1, \ldots, 5 \), at \( \gamma = 1, \ f_{\infty} = 0 \).

Table 10.6: Commands for running demo kar.
10.7  spb : A Singularly-Perturbed BVP.

This demo illustrates the use of continuation to compute solutions to the singularly perturbed boundary value problem

\[
\begin{align*}
    u_1' &= u_2, \\
    u_2' &= \lambda \epsilon (u_1 u_2 (u_2^2 - 1) + u_1),
\end{align*}
\]

(10.10)

with boundary conditions \( u_1(0) = 3/2, \ u_1(1) = \gamma \). The parameter \( \lambda \) has been introduced into the equations in order to allow a homotopy from a simple equation with known exact solution to the actual equation. This is done in the first run. In the second run \( \epsilon \) is decreased by continuation. In the third run \( \epsilon \) is fixed at \( \epsilon = .001 \) and the solution is continued in \( \gamma \). This run takes more than 1500 continuation steps. For a detailed analysis of the solution behavior see Lorenz (1982).

10.8  

**ezp : Complex Bifurcation in a BVP.**

This demo illustrates the computation of a solution branch to the the complex boundary value problem

\[
\begin{align*}
u_1' &= u_2, \\
u_2' &= -p_1 e^{u_1},
\end{align*}
\]  

(10.11)

with boundary conditions \( u_1(0) = 0, \; u_1(1) = 0 \). Here \( u_1 \) and \( u_2 \) are allowed to be complex, while the parameter \( p_1 \) can only take real values. In the real case, this is Bratu's equation, whose solution branch contains a fold; see the demo *exp*. It is known (Henderson & Keller (1990)) that a simple quadratic fold gives rise to a pitch fork bifurcation in the complex equation. This bifurcation is located in the first computation below. In the second and third run, both legs of the bifurcating solution branch are computed. On it, both solution components \( u_1 \) and \( u_2 \) have nontrivial imaginary part.

Table 10.8: Commands for running demo *ezp.*
Chapter 11

AUTO Demos : Parabolic PDEs.
11.1  pd1 : Stationary States (1D Problem).

This demo uses Euler's method to locate a stationary solution of a nonlinear parabolic PDE, followed by continuation of this stationary state in a free problem parameter. The equation is

\[ \frac{\partial u}{\partial t} = D \frac{\partial^2 u}{\partial x^2} + p_1 u (1 - u), \]

on the space interval \([0, L]\), where \(L = \text{PAR}(11) = 10\) is fixed throughout, as is the diffusion constant \(D = \text{PAR}(15) = 0.1\). The boundary conditions are \(u(0) = u(L) = 0\) for all time.

In the first run the continuation parameter is the independent time variable, namely \(\text{PAR}(14)\), while \(p_1 = 1\) is fixed. The AUTO -constants \(\text{DS}, \text{DSMIN}, \text{DSMAX}\) then control the step size in space-time, here consisting of \(\text{PAR}(14)\) and \(u(x)\). Initial data are \(u(x) = \sin(\pi x / L)\) at time zero. Note that in the subroutine \(\text{stput}\) the initial data must be scaled to the unit interval, and that the scaled derivative must also be provided; see the equations-file \(\text{pv1.c}\). In the second run the continuation parameter is \(p_1\).

Euler time integration is only first order accurate, so that the time step must be sufficiently small to ensure correct results. Indeed, this option has been added only as a convenience, and should generally be used only to locate stationary states.

<table>

</tbody>
</table>

Table 11.1: Commands for running demo pd1.
11.2 pd2 : Stationary States (2D Problem).

This demo uses Euler’s method to locate a stationary solution of a nonlinear parabolic PDE, followed by continuation of this stationary state in a free problem parameter. The equations are

\[
\begin{align*}
\frac{\partial u_1}{\partial t} &= D_1 \frac{\partial^2 u_1}{\partial x^2} + p_1 u (1 - u) - u_1 u_2, \\
\frac{\partial u_2}{\partial t} &= D_2 \frac{\partial^2 u_2}{\partial x^2} - u_2 + u_1 u_2,
\end{align*}
\tag{11.1}
\]

on the space interval \([0, L]\), where \(L = \text{PAR}(11) = 1\) is fixed throughout, as are the diffusion constants \(D_1 = \text{PAR}(15) = 1\) and \(D_2 = \text{PAR}(16) = 1\). The boundary conditions are \(u_1(0) = u_1(L) = 0\) and \(u_2(0) = u_2(L) = 1\), for all time.

In the first run the continuation parameter is the independent time variable, namely \(\text{PAR}(14)\), while \(p_1 = 12\) is fixed. The AUTO -constants \(\text{DS}, \text{DSMIN}, \text{DSMAX}\) then control the step size in space-time, here consisting of \(\text{PAR}(14)\) and \((u_1(x), u_2(x))\). Initial data at time zero are \(u_1(x) = \sin(\pi x/L)\) and \(u_2(x) = 1\). Note that in the subroutine \text{stpt}nt the initial data must be scaled to the unit interval, and that the scaled derivatives must also be provided; see the equations-file \text{pv2.c}. In the second run the continuation parameter is \(p_1\). A branch point is located during this run.

Euler time integration is only first order accurate, so that the time step must be sufficiently small to ensure correct results. Indeed, this option has been added only as a convenience, and should generally be used only to locate stationary states.

Table 11.3: Commands for running demo wav.
11.4  brc : Chebyshev Collocation in Space.

This demo illustrates the computation of stationary solutions and periodic solutions to systems of parabolic PDEs in one space variable, using Chebyshev collocation in space. More precisely, the approximate solution is assumed of the form $u(x,t) = \sum_{k=0}^{n+1} u_k(t) \ell_k(x)$. Here $u_k(t)$ corresponds to $u(x_k,t)$ at the Chebyshev points $\{x_k\}_{k=1}^{n}$ with respect to the interval $[0,1]$. The polynomials $\{\ell_k(x)\}_{k=0}^{n+1}$ are the Lagrange interpolating coefficients with respect to points $\{x_k\}_{k=0}^{n+1}$, where $x_0 = 0$ and $x_{n+1} = 1$. The number of Chebyshev points in $[0,1]$, as well as the number of equations in the PDE system, can be set by the user in the file brc.inc.

As an illustrative application we consider the Brusselator (Holodniok, Knedlik & Kubíček (1987))

\[
\begin{align*}
    u_t &= D_x/L^2 u_{xx} + u^2 v - (B + 1)u + A, \\
    v_t &= D_y/L^2 v_{xx} - u^2 v + Bu,
\end{align*}
\]

with boundary conditions $u(0,t) = u(1,t) = A$ and $v(0,t) = v(1,t) = B/A$.

Note that, given the non-adaptive spatial discretization, the computational procedure here is not appropriate for PDEs with solutions that rapidly vary in space, and care must be taken to recognize spurious solutions and bifurcations.

</tr>
</tbody>
</table>

Table 11.4: Commands for running demo brc.
11.5 bfr : Finite Differences in Space.

This demo illustrates the computation of stationary solutions and periodic solutions to systems of parabolic PDEs in one space variable. A fourth order accurate finite difference approximation is used to approximate the second order space derivatives. This reduces the PDE to an autonomous ODE of fixed dimension which AUTO is capable of treating. The spatial mesh is uniform; the number of mesh intervals, as well as the number of equations in the PDE system, can be set by the user in the file bfr.inc.

As an illustrative application we consider the Brusselator (Holodniok, Knedlik & Kubíček (1987))

\[
\begin{align*}
    u_t &= D_x/L^2 u_{xx} + u^2 v - (B + 1)u + A, \\
    v_t &= D_y/L^2 v_{xx} - u^2 v + Bu,
\end{align*}
\]

with boundary conditions \( u(0,t) = u(1,t) = A \) and \( v(0,t) = v(1,t) = B/A \).

Note that, given the non-adaptive spatial discretization, the computational procedure here is not appropriate for PDEs with solutions that rapidly vary in space, and care must be taken to recognize spurious solutions and bifurcations.

</tr>
</tbody>
</table>

Table 11.5: Commands for running demo bfr.
11.6 bru : Euler Time Integration (the Brusselator).

This demo illustrates the use of Euler’s method for time integration of a nonlinear parabolic PDE. The example is the Brusselator (Holodník, Knědlík & Kubíček (1987)), given by

\[
\begin{align*}
    u_t &= D_x/L^2 u_{xx} + u^2 v - (B + 1)u + A, \\
    v_t &= D_y/L^2 v_{xx} - u^2 v + Bu, \\
\end{align*}
\]  \hspace{1cm} (11.5)

with boundary conditions \( u(0,t) = u(1,t) = A \) and \( v(0,t) = v(1,t) = B/A \). All parameters are given fixed values for which a stable periodic solution is known to exist.

The continuation parameter is the independent time variable, namely \( \text{PAR}(14) \). The AUTO-constants \( \text{DS} \), \( \text{DSMIN} \), and \( \text{DSMAX} \) then control the step size in space-time, here consisting of \( \text{PAR}(14) \) and \((u(x),v(x))\). Initial data at time zero are \( u(x) = A - 0.5 \sin(\pi x) \) and \( v(x) = B/A + 0.7 \sin(\pi x) \). Note that in the subroutine \( \text{stpnt} \) the space derivatives of \( u \) and \( v \) must also be provided; see the equations-file \( \text{bru.c} \).

Euler time integration is only first order accurate, so that the time step must be sufficiently small to ensure correct results. This option has been added only as a convenience, and should generally be used only to locate stationary states. Indeed, in the case of the asymptotic periodic state of this demo, the number of required steps is very large and use of a better time integrator is advisable.

Table 12.1: Commands for running demo opt.
12.2 ops : Optimization of Periodic Solutions.

This demo illustrates the method of successive continuation for the optimization of periodic solutions. For a detailed description of the basic method see Doedel, Keller & Kernévez (1991b). The illustrative system of autonomous ODEs, taken from Rodríguez-Luis (1991), is

\[
\begin{align*}
    x'(t) &= [-\lambda_4(x^3/3 - x) + (z - x)/\lambda_2 - y]/\lambda_1, \\
    y'(t) &= x - \lambda_3, \\
    z'(t) &= -(z - x)/\lambda_2,
\end{align*}
\]  

(12.1)

with objective functional

\[
\omega = \int_0^1 g(x, y, z; \lambda_1, \lambda_2, \lambda_3, \lambda_4) \, dt,
\]

where \(g(x, y, z; \lambda_1, \lambda_2, \lambda_3, \lambda_4) \equiv \lambda_3\). Thus, in this application, a one-parameter extremum of \(g\) corresponds to a fold with respect to the problem parameter \(\lambda_3\), and multi-parameter extrema correspond to generalized folds. Note that, in general, the objective functional is an integral along the periodic orbit, so that a variety of optimization problems can be addressed.

For the case of periodic solutions, the extended optimality system can be generated automatically, i.e., one need only define the vector field and the objective functional, as in done in the file ops.c. For reference purpose it is convenient here to write down the full extended system in its general form :

\[
\begin{align*}
    u'(t) &= Tf(u(t), \lambda), \quad T \in \mathbb{R} \text{ (period)}, \quad u(\cdot), f(\cdot, \cdot) \in \mathbb{R}^n, \quad \lambda \in \mathbb{R}^{n\lambda}, \\
    w'(t) &= -Tf_u(u(t), \lambda)^* w(t) + \kappa u'_0(t) + \gamma g_u(u(t), \lambda)^*, \quad w(\cdot) \in \mathbb{R}^n, \quad \kappa, \gamma \in \mathbb{R}, \\
    u(1) - u(0) &= 0, \quad w(1) - w(0) = 0, \\
    \int_0^1 u(t)^* u'_0(t) \, dt &= 0, \\
    \int_0^1 \omega - g(u(t), \lambda) \, dt &= 0, \\
    \int_0^1 w(t)^* w(t) + \kappa^2 + \gamma^2 - \alpha \, dt &= 0, \quad \alpha \in \mathbb{R}, \\
    \int_0^1 f(u(t), \lambda)^* w(t) - \gamma g_T(u(t), \lambda) - \tau_0 \, dt &= 0, \quad \tau_0 \in \mathbb{R}, \\
    \int_0^1 T f_{\lambda_i}(u(t), \lambda)^* w(t) - \gamma g_{\lambda_i}(u(t), \lambda) - \tau_i \, dt &= 0, \quad \tau_i \in \mathbb{R}, \quad i = 1, \cdots, n\lambda.
\end{align*}
\]  

(12.2)

Above \(u_0\) is a reference solution, namely, the previous solution along a solution branch.
In the computations below, the two preliminary runs, with \textbf{IPS}=1 and \textbf{IPS}=2, respectively, locate periodic solutions. The subsequent runs are with \textbf{IPS}=15 and hence use the automatically generated extended system.

- **Run 1.** Locate a Hopf bifurcation. The free system parameter is $\lambda_3$.

- **Run 2.** Compute a branch of periodic solutions from the Hopf bifurcation.

- **Run 3.** This run retraces part of the periodic solution branch, using the full optimality system, but with all adjoint variables, $w(\cdot), \kappa, \gamma,$ and hence $\alpha$, equal to zero. The optimality parameters $\tau_0$ and $\tau_3$ are zero throughout. An extremum of the objective functional with respect to $\lambda_3$ is located. Such a point corresponds to a branch point of the extended system. Given the choice of objective functional in this demo, this extremum is also a fold with respect to $\lambda_3$.

- **Run 4.** Branch switching at the above-found branch point yields nonzero values of the adjoint variables. Any point on the bifurcating branch away from the branch point can serve as starting solution for the next run. In fact, the branch-switching can be viewed as generating a nonzero eigenvector in an eigenvalue-eigenvector relation. Apart from the adjoint variables, all other variables remain unchanged along the bifurcating branch.

- **Run 5.** The above-found starting solution is continued in two system parameters, here $\lambda_3$ and $\lambda_2$; i.e., a two-parameter branch of extrema with respect to $\lambda_3$ is computed. Along this branch the value of the optimality parameter $\tau_2$ is monitored, i.e., the value of the functional that vanishes at an extremum with respect to the system parameter $\lambda_2$. Such a zero of $\tau_2$ is, in fact, located, and hence an extremum of the objective functional with respect to both $\lambda_2$ and $\lambda_3$ has been found. Note that, in general, $\tau_i$ is the value of the functional that vanishes at an extremum with respect to the system parameter $\lambda_i$.

- **Run 6.** In the final run, the above-found two-parameter extremum is continued in three system parameters, here $\lambda_1$, $\lambda_2$, and $\lambda_3$, toward $\lambda_1 = 0$. Again, given the particular choice of objective functional, this final continuation has an alternate significance here: it also represents a three-parameter branch of transcritical secondary periodic bifurcations points.

Although not illustrated here, one can restart an ordinary continuation of periodic solutions, using \textbf{IPS}=2 or \textbf{IPS}=3, from a labeled solution point on a branch computed with \textbf{IPS}=15.
The free scalar variables specified in the AUTO constants-files for Run 3 and Run 4 are shown in Table 12.2.

Table 12.2: Runs 3 and 4 (files c.ops.3 and c.ops.4).

<table>
<thead>
<tr>
<th>Index</th>
<th>3</th>
<th>11</th>
<th>12</th>
<th>22</th>
<th>-22</th>
<th>-23</th>
<th>-31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>$\lambda_3$</td>
<td>$T$</td>
<td>$\alpha$</td>
<td>$\tau_2$</td>
<td>$[\lambda_2]$</td>
<td>$[\lambda_3]$</td>
<td>$[T]$</td>
</tr>
</tbody>
</table>

The parameter $\alpha$, which is the norm of the adjoint variables, becomes nonzero after branch switching in Run 4. The negative indices (-22, -23, and -31) set the active optimality functionals, namely for $\lambda_2$, $\lambda_3$, and $T$, respectively, with corresponding variables $\tau_2$, $\tau_3$, and $\tau_0$, respectively. These should be set in the first run with IPS=15 and remain unchanged in all subsequent runs.

Table 12.3: Run 5 (file c.ops.5).

<table>
<thead>
<tr>
<th>Index</th>
<th>3</th>
<th>2</th>
<th>11</th>
<th>22</th>
<th>-22</th>
<th>-23</th>
<th>-31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>$\lambda_3$</td>
<td>$\lambda_2$</td>
<td>$T$</td>
<td>$\tau_2$</td>
<td>$[\lambda_2]$</td>
<td>$[\lambda_3]$</td>
<td>$[T]$</td>
</tr>
</tbody>
</table>

In Run 5 the parameter $\alpha$, which has been replaced by $\lambda_2$, remains fixed and nonzero. The variable $\tau_2$ monitors the value of the optimality functional associated with $\lambda_2$. The zero of $\tau_2$ located in this run signals an extremum with respect to $\lambda_2$.

Table 12.4: Run 6 (file c.ops.6).

<table>
<thead>
<tr>
<th>Index</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>11</th>
<th>-22</th>
<th>-23</th>
<th>-31</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>$\lambda_3$</td>
<td>$\lambda_2$</td>
<td>$\lambda_1$</td>
<td>$T$</td>
<td>$[\lambda_2]$</td>
<td>$[\lambda_3]$</td>
<td>$[T]$</td>
</tr>
</tbody>
</table>

In Run 6 $\tau_2$, which has been replaced by $\lambda_1$, remains zero. Note that $\tau_0$ and $\tau_3$ are not used as variables in any of the runs; in fact, their values remain zero throughout. Also note that the optimality functionals corresponding to $\tau_0$ and $\tau_3$ (or, equivalently, to $T$ and $\lambda_3$) are active in all runs. This set-up allows the detection of the extremum of the objective functional, with $T$ and $\lambda_3$ as scalar equation parameters, as a bifurcation in the third run.

The parameter $\lambda_4$, and its corresponding optimality variable $\tau_4$, are not used in this demo. Also, $\lambda_1$ is used in the last run only, and its corresponding optimality variable $\tau_1$ is never used.

Table 12.5: Commands for running demo ops.
12.3 obv : Optimization for a BVP.

This demo illustrates use of the method of successive continuation for a boundary value optimization problem. A detailed description of the basic method, as well as a discussion of the specific application considered here, is given in Doedel, Keller & Kernévez (1991b). The required extended system is fully programmed here in the user-supplied subroutines in obv.c. For the case of periodic solutions the optimality system can be generated automatically; see the demo ops.

Consider the system

\[
\begin{align*}
    u_1'(t) &= u_2(t), \\
    u_2'(t) &= -\lambda_1 e^{p(u_1, \lambda_2, \lambda_3)}, \\
    w_1'(t) &= \lambda_1 e^{p(u_1, \lambda_2, \lambda_3)} p_{u_1} w_2(t) + 2\gamma (u_1(t) - 1), \\
    w_2'(t) &= -w_1(t),
\end{align*}
\]  

(12.3)

where \( p(u_1, \lambda_2, \lambda_3) \equiv u_1 + \lambda_2 u_1^2 + \lambda_3 u_1^4 \), with boundary conditions

\[
\begin{align*}
    u_1(0) &= 0, \\
    u_1(1) &= 0.
\end{align*}
\]  

(12.4)

The objective functional is

\[
\omega = \int_0^1 (u_1(t) - 1)^2 \, dt + \frac{1}{10} \sum_{k=1}^3 \lambda_k^2.
\]

The successive continuation equations are given by

\[
\begin{align*}
    u_1'(t) &= u_2(t), \\
    u_2'(t) &= -\lambda_1 e^{p(u_1, \lambda_2, \lambda_3)}, \\
    w_1'(t) &= \lambda_1 e^{p(u_1, \lambda_2, \lambda_3)} p_{u_1} w_2(t) + 2\gamma (u_1(t) - 1), \\
    w_2'(t) &= -w_1(t),
\end{align*}
\]  

(12.5)

where

\[
p_{u_1} \equiv \frac{\partial p}{\partial u_1} = 1 + 2\lambda_2 u_1 + 4\lambda_3 u_1^3,
\]

with

\[
\begin{align*}
    u_1(0) &= 0, & w_1(0) - \beta_1 &= 0, & w_2(0) &= 0, \\
    u_1(1) &= 0, & w_1(1) + \beta_2 &= 0, & w_2(1) &= 0,
\end{align*}
\]  

(12.6)

\[
\int_0^1 [\omega - (u_1(t) - 1)^2 - \frac{1}{10} \sum_{k=1}^3 \lambda_k^2] \, dt = 0,
\]

\[
\int_0^1 [w_1^2(t) - \alpha_0] \, dt = 0,
\]

\[
\int_0^1 [-e^{p(u_1, \lambda_2, \lambda_3)} w_2(t) - \frac{1}{5} \gamma \lambda_1] \, dt = 0,
\]

\[
\int_0^1 [-\lambda_1 e^{p(u_1, \lambda_2, \lambda_3)} u_1(t)^2 w_2(t) - \frac{1}{5} \gamma \lambda_2 - \tau_2] \, dt = 0,
\]

\[
\int_0^1 [-\lambda_1 e^{p(u_1, \lambda_2, \lambda_3)} u_1(t)^4 w_2(t) - \frac{1}{5} \gamma \lambda_3 - \tau_3] \, dt = 0.
\]  

(12.7)

In the first run the free equation parameter is \( \lambda_1 \). All adjoint variables are zero. Three extrema of the objective function are located. These correspond to branch points and, in the second run, branch switching is done at one of these. Along the bifurcating branch the adjoint
variables become nonzero, while state variables and $\lambda_1$ remain constant. Any such non-trivial solution point can be used for continuation in two equation parameters, after fixing the $L_2$-norm of one of the adjoint variables. This is done in the third run. Along the resulting branch several two-parameter extrema are located by monitoring certain inner products. One of these is further continued in three equation parameters in the final run, where a three-parameter extremum is located.

Table 12.6: Commands for running demo obv.
Chapter 13

AUTO Demos: Connecting orbits.
13.1 \( \text{fsh} : \text{A Saddle-Node Connection.} \)

This demo illustrates the computation of travelling wave front solutions to the Fisher equation,

\[
\begin{align*}
    w_t &= w_{xx} + f(w), \quad -\infty < x < \infty, \quad t > 0, \\
    f(w) &\equiv w(1 - w).
\end{align*}
\] (13.1)

We look for solutions of the form \( w(x, t) = u(x + ct) \), where \( c \) is the wave speed. This gives the first order system

\[
\begin{align*}
    u'_1(z) &= u_2(z), \\
    u'_2(z) &= cu_2(z) - f(u_1(z)).
\end{align*}
\] (13.2)

Its fixed point \((0,0)\) has two positive eigenvalues when \( c > 2 \). The other fixed point, \((1,0)\), is a saddle point. A branch of orbits connecting the two fixed points requires one free parameter; see Friedman & Doedel (1991). Here we take this parameter to be the wave speed \( c \).

In the first run a starting connecting orbit is computed by continuation in the period \( T \). This procedure can be used generally for time integration of an ODE with AUTO. Starting data in \textit{stpnt} correspond to a point on the approximate stable manifold of \((1,0)\), with \( T \) small. In this demo the “free” end point of the orbit necessary approaches the unstable fixed point \((0,0)\). A computed orbit with sufficiently large \( T \) is then chosen as restart orbit in the second run, where, typically, one replaces \( T \) by \( c \) as continuation parameter. However, in the second run below, we also add a phase condition, and both \( c \) and \( T \) remain free.

<table>

</tbody>
</table>

Table 13.1: Commands for running demo \textit{fsh}. 

130
13.2 nag : A Saddle-Saddle Connection.

This demo illustrates the computation of traveling wave front solutions to Nagumo’s equation,

\begin{align*}
  w_t &= w_{xx} + f(w, a), \quad -\infty < x < \infty, \quad t > 0, \\
  f(w, a) &\equiv w(1 - w)(w - a), \quad 0 < a < 1.
\end{align*}

(13.3)

We look for solutions of the form \(w(x, t) = u(x + ct)\), where c is the wave speed. This gives the first order system

\begin{align*}
  u'_1(z) &= u_2(z), \\
  u'_2(z) &= cu_2(z) - f(u_1(z), a),
\end{align*}

(13.4)

where \(z = x + ct\), and \(’ = d/dz\). If \(a = 1/2\) and \(c = 0\) then there are two analytically known heteroclinic connections, one of which is given by

\begin{align*}
  u_1(z) &= \frac{e^{\frac{1}{2}\sqrt{2z}}}{1 + e^{\frac{1}{2}\sqrt{2z}}}, \\
  u_2(z) &= u'_1(z), \quad -\infty < z < \infty.
\end{align*}

The second heteroclinic connection is obtained by reflecting the phase plane representation of the first with respect to the \(u_1\)-axis. In fact, the two connections together constitute a heteroclinic cycle. One of the exact solutions is used below as starting orbit. To start from the second exact solution, change SIGN=-1 in the subroutine \texttt{stptnt} in \texttt{nag.c} and repeat the computations below; see also Friedman & Doedel (1991).

131
13.3 stw : Continuation of Sharp Traveling Waves.

This demo illustrates the computation of sharp traveling wave front solutions to nonlinear diffusion problems of the form

\[ w_t = A(w)w_{xx} + B(w)w_x^2 + C(w), \]

with \( A(w) = a_1 w + a_2 w^2 \), \( B(w) = b_0 + b_1 w + b_2 w^2 \), and \( C(w) = c_0 + c_1 w + c_2 w^2 \). Such equations can have sharp traveling wave fronts as solutions, i.e., solutions of the form \( w(x,t) = u(x+ct) \) for which there is a \( z_0 \) such that \( u(z) = 0 \) for \( z \geq z_0 \), \( u(z) \neq 0 \) for \( z < z_0 \), and \( u(z) \to \text{constant} \) as \( z \to -\infty \). These solutions are actually generalized solutions, since they need not be differentiable at \( z_0 \).

Specifically, in this demo a homotopy path will be computed from an analytically known exact sharp traveling wave solution of

\[ (1) \quad w_t = 2ww_{xx} + 2w_x^2 + w(1-w), \]

to a corresponding sharp traveling wave of

\[ (2) \quad w_t = (2w + w^2)w_{xx} + ww_x^2 + w(1-w). \]

This problem is also considered in Doedel, Keller & Kernévez (1991b). For these two special cases the functions \( A, B, C \) are defined by the coefficients in Table 13.3.

<td>-1</td>
<td></td>
</tr>
</tbody>
</table>

Table 13.3: Problem coefficients in demo stw.

With \( w(x,t) = u(x+ct) \), \( z = x+ct \), one obtains the reduced system

\[
\begin{align*}
  u'_1(z) &= u_2, \\
  u'_2(z) &= \left[ cu_2 - B(u_1)u_2^2 - C(u_1) \right]/A(u_1).
\end{align*}
\]

(13.5)

To remove the singularity when \( u_1 = 0 \), we apply a nonlinear transformation of the independent variable (see Aronson (1980)), viz., \( d/d\tilde{z} = A(u_1)d/dz \), which changes the above equation into

\[
\begin{align*}
  u'_1(\tilde{z}) &= A(u_1)u_2, \\
  u'_2(\tilde{z}) &= cu_2 - B(u_1)u_2^2 - C(u_1).
\end{align*}
\]

(13.6)

Sharp traveling waves then correspond to heteroclinic connections in this transformed system.
Finally, we map \([0, T] \rightarrow [0, 1]\) by the transformation \(\xi = \tilde{z}/T\). With this scaling of the independent variable, the reduced system becomes
\[
\begin{align*}
u_1'(\xi) &= TA(u_1)u_2, \\
u_2'(\xi) &= T[cu_2 - B(u_1)u_2^2 - C(u_1)].
\end{align*}
\tag{13.7}
\]

For Case 1 this equation has a known exact solution, namely,
\[
\begin{align*}u(\xi) &= \frac{1}{1 + \exp(T\xi)}, \\
v(\xi) &= \frac{-1/2}{1 + \exp(-T\xi)}.
\end{align*}
\]

This solution has wave speed \(c = 1\). In the limit as \(T \rightarrow \infty\) its phase plane trajectory connects the stationary points \((1, 0)\) and \((0, -1/2)\).

The sharp traveling wave in Case 2 can now be obtained using the following homotopy. Let \((a_1, a_2, b_0, b_1, b_2) = (1 - \lambda)(2, 0, 2, 0, 0) + \lambda(2, 1, 0, 1, 0)\). Then as \(\lambda\) varies continuously from 0 to 1, the parameters \((a_1, a_2, b_0, b_1, b_2)\) vary continuously from the values for Case 1 to the values for Case 2.

Chapter 14

AUTO Demos : Miscellaneous.
14.1  pvl : Use of the Subroutine pvls.

Consider Bratu’s equation

\[ \begin{align*}
  u_1' &= u_2, \\
  u_2' &= -p_1 e^{u_1},
\end{align*} \tag{14.1} \]

with boundary conditions \( u_1(0) = 0, \ u_1(1) = 0 \). As in demo exp, a solution curve requires one free parameter; here \( p_1 \).

Note that additional parameters are specified in the user-supplied subroutine pvls in file pvls.c, namely, \( p_2 \) (the \( L_2 \)-norm of \( u_1 \)), \( p_3 \) (the minimum of \( u_2 \) on the space-interval \([0, 1]\)) , \( p_4 \) (the boundary value \( u_2(0) \)). These additional parameters should be considered as "solution measures" for output purposes; they should not be treated as true continuation parameters.

Note also that four free parameters are specified in the AUTO-constants file c.pvl.1, namely, \( p_1, p_2, p_3, \) and \( p_4 \). The first one in this list, \( p_1 \), is the true continuation parameter. The parameters \( p_2, p_3, \) and \( p_4 \) are overspecified so that their values will appear in the output. However, it is essential that the true continuation parameter appear first. For example, it would be an error to specify the parameters in the following order: \( p_2, p_1, p_3, p_4 \).

In general, true continuation parameters must appear first in the parameter-specification in the AUTO constants-file. Overspecified parameters will be printed, and can be defined in pvls, but they are not part of the intrinsic continuation procedure.

As this demo also illustrates (see the UZR values in c.pvl.1), labeled solutions can also be output at selected values of the overspecified parameters.

14.2 ext : Spurious Solutions to BVB.

This demo illustrates the computation of spurious solutions to the boundary value problem

\[
\begin{align*}
    u'_1 - u_2 & = 0, \\
    u'_2 + \lambda^2 \pi^2 \sin(u_1 + u_1^2 + u_3) & = 0, \quad t \in [0, 1], \\
    u_1(0) & = 0, \quad u_1(1) = 0.
\end{align*}
\] (14.2)

Here the differential equation is discretized using a fixed uniform mesh. This results in spurious solutions that disappear when an adaptive mesh is used. See the AUTO -constant \texttt{IAD} in Section 5.3. This example is also considered in Beyn & Doedel (1981) and Doedel, Keller & Kernévez (1991b).

14.3 tim: A Test Problem for Timing AUTO.

This demo is a boundary value problem with variable dimension $\text{NDIM}$. It can be used to time the performance of AUTO for various choices of $\text{NDIM}$ (which must be even), $\text{NTST}$, and $\text{NCOL}$. The equations are

$$
\begin{align*}
  u'_i &= u_i, \\
  v'_i &= -p_1 e(u_i),
\end{align*}
$$

$i = 1, \ldots, \text{NDIM}/2$, with boundary conditions $u_i(0) = 0, u_i(1) = 0$. Here

$$
e(u) = \sum_{k=0}^{n} \frac{u^k}{k!},$$

with $n = 25$. The computation requires 10 full $LU$-decompositions of the linearized system that arises from Newton’s method for solving the collocation equations. The commands for running the timing problem for a particular choice of $\text{NDIM}$, $\text{NTST}$, and $\text{NCOL}$ are given below. (Note that if $\text{NDIM}$ is changed then $\text{NBC}$ must be changed accordingly.)

Chapter 15

HomCont.

15.1 Introduction.

HomCont is a collection of subroutines for the continuation of homoclinic solutions to ODEs in two or more parameters. The accurate detection and multi-parameter continuation of certain codimension-two singularities is allowed for, including all known cases that involve a unique homoclinic orbit at the singular point. Homoclinic connections to hyperbolic and non-hyperbolic equilibria are allowed as are certain heteroclinic orbits. Homoclinic orbits in reversible systems can also be computed. The theory behind the methods used is explained in Champneys & Kuznetsov (1994), Bai & Champneys (1996), Sandstede (1995b, 1995c), Champneys, Kuznetsov & Sandstede (1996) and references therein. The final cited paper contains a concise description of the present version.

The current implementation of HomCont must be considered as experimental, and updates are anticipated. The HomCont subroutines are in the file auto/2000/src/autlib5.c. Expert users wishing to modify the routines may look there. Note also that at present, HomCont can be run only in AUTO Command Mode and not with the GUI.

15.2 HomCont Files and Subroutines.

In order to run HomCont one must prepare an equations file xxx.c, where xxx is the name of the example, and two constants-files c.xxx and h.xxx. The first two of these files are in the standard AUTO format, whereas the h.xxx file contains constants that are specific to homoclinic continuation. The choice IPS=9 in c.xxx specifies the problem as being homoclinic continuation, in which case h.xxx is required.

The equation-file kpr.c serves as a sample for new equation files. It contains the C subroutines func, stpnt, pvls, bcond, icnd and fopt. The final three are dummy subroutines which are never needed for homoclinic continuation. Note a minor difference in stpnt and pvls with other AUTO equation-files, in that the common block /BLHOM/ is required.

The constants-file c.xxx is identical in format to other AUTO constants-files. Note that the values of the constants NBC and NINT are irrelevant, as these are set automatically by the choice IPS=9. Also, the choice JAC=1 is strongly recommended, because the Jacobian is used extensively for calculating the linearization at the equilibria and hence for evaluating boundary
conditions and certain test functions. However, note that \( \text{JAC}=1 \) does not necessarily mean that auto will use the analytically specified Jacobian for continuation.

### 15.3 HomCont-Constants.

An example for the additional file \( h.xxx \) is listed below:

```
1 2 1 1 1 NUNSTAB,NSTAB,IEQUIB,ITWIST,ISTART
0 NREV,(/,I,IREV(I)),I=1,NREV)
1 NFIXED,(/,I,IFIXED(I)),I=1,NFIXED)
13
1 NPSI,(/,I,IPSI(I)),I=1,NPSI)
9 10 13
```

The constants specified in \( h.xxx \) have the following meaning.

#### 15.3.1 NUNSTAB

Number of unstable eigenvalues of the left-hand equilibrium (the equilibrium approached by the orbit as \( t \to -\infty \)).

#### 15.3.2 NSTAB

Number of stable eigenvalues of the right-hand equilibrium (the equilibrium approached by the orbit as \( t \to +\infty \)).

#### 15.3.3 IEQUIB

- \( \text{IEQUIB}=0 \): Homoclinic orbits to hyperbolic equilibria; the equilibrium is specified explicitly in \( \text{pvls} \) and stored in \( \text{par}[10+I], \; I=1,\text{NDIM} \).

- \( \text{IEQUIB}=1 \): Homoclinic orbits to hyperbolic equilibria; the equilibrium is solved for during continuation. Initial values for the equilibrium are stored in \( \text{par}[10+I], \; I=1,\text{NDIM} \) in \( \text{stpnt} \).

- \( \text{IEQUIB}=2 \): Homoclinic orbits to a saddle-node; initial values for the equilibrium are stored in \( \text{par}[10+I], \; I=1,\text{NDIM} \) in \( \text{stpnt} \).

- \( \text{IEQUIB}=-1 \): Heteroclinic orbits to hyperbolic equilibria; the equilibria are specified explicitly in \( \text{pvls} \) and stored in \( \text{par}[10+I], \; I=1,\text{NDIM} \) (left-hand equilibrium) and \( \text{par}[10+I], \; I=\text{NDIM}+1,2*\text{NDIM} \) (right-hand equilibrium).

- \( \text{IEQUIB}=-2 \): Heteroclinic orbits to hyperbolic equilibria; the equilibria are solved for during continuation. Initial values are specified in \( \text{stpnt} \) and stored in \( \text{par}[10+I], \; I=1,\text{NDIM} \) (left-hand equilibrium), \( \text{par}[10+I], \; I=\text{NDIM}+1,2*\text{NDIM} \) (right-hand equilibrium).
15.3.4 ITWIST

- ITWIST=0: the orientation of the homoclinic orbit is not computed.

- ITWIST=1: the orientation of the homoclinic orbit is computed. For this purpose, the adjoint variational equation is solved for the unique bounded solution. If IRS = 0, an initial solution to the adjoint equation must be specified as well. However, if IRS>0 and ITWIST has just been increased from zero, then AUTO will automatically generate the initial solution to the adjoint. In this case, a dummy Newton-step should be performed, see Section 15.7 for more details.

15.3.5 ISTART

- ISTART=1: This option is obsolete in the current version. It may be used as a flag that a solution is to be restarted from a previously computed point or from numerical data converted into AUTO format using us. In this case IRS>0.

- ISTART=2: If IRS=0, an explicit solution must be specified in the subroutine stpnt in the usual format.

- ISTART=3: The “homotopy” approach is used for starting, see Section 15.7 for more details. Note that this is not available with the choice IEQUIB=2.

- ISTART=4: A phase-shift is performed for homoclinic orbits to let the equilibrium (either fixed or non-fixed, depending on IEQUIB) correspond to \( t = 0 \) and \( t = 1 \). This is necessary if a periodic orbit that is close to a homoclinic orbit is continued into a homoclinic orbit.

- ISTART=-N, \( N = 1, 2, 3, \ldots \): Homoclinic branch switching: this description is for reference only and we refer to Chapter 22 to see how this can be used in actual practice and to Oldeman, Champneys & B. (2001) for theory and background.

The orbit is split into \( N + 1 \) parts and AUTO sees it as an \( (N + 1) \times \text{NDIM} \)-dimensional object. The first part \( u_0 \) goes from the equilibrium to the point \( x_0 \) that is furthest from the equilibrium. Then follow \( N - 1 \) shifted copies of the orbit, which travel from the point \( x_0 \) back to the point \( x_0 \). The last part \( U_N \) goes from the point \( x_0 \) back to the equilibrium. The derivatives \( \dot{x}_0 \) with respect to time of the point that is furthest from the equilibrium are stored at the parameters par[\text{NPARX-NDIM}...\text{NPARX-1}].

If ITWIST=1, and this was also the case in the preceding run, then a copy of the adjoint vector \( \Psi \) at \( x_0 \) is stored at the parameters par[\text{NPARX-NDIM+2}...\text{NPARX-NDIM-1}] and Lin’s method can be used to do homoclinic branch switching. To be more precise, the individual parts \( u_i \) and \( u_{i+1} \) are at distances \( \varepsilon_i \) away from each other, along the Lin vector \( P_{si} \), at the left- and right-hand end points. These gaps \( \varepsilon_i \) are at parameters par[19+2*i]. Moreover, each part (except \( u_{N+1} \)) ends at at a Poincaré section which goes through \( x_0 \) and is perpendicular to \( \dot{x}_0 \).

The times \( T_i \) that each part \( u_i \) takes are stored as follows: \( T_0 = \text{par}[9] \), \( T_N = \text{par}[10] \) and \( T_i = \text{par}[18+2*i] \) for \( i = 1 \ldots N - 1 \). Through a continuation in problem parameters, gaps \( \varepsilon_i \), and times \( T_i \) it is possible to switch from a 1-homoclinic to an \( N \)-homoclinic orbit.
If $\text{ITWIST}=0$, the adjoint vector is not computed and Lin’s method is not used. Instead, AUTO produces a gap $\varepsilon=\text{par}[21]$ at the right-hand end point $p$ of $u_{N+1}$, measuring the distance between the stable manifold of the equilibrium and $p$. This technique can also be used to find 2-homoclinic orbits, by varying in $\varepsilon$ and $T_1$, similar to the method described before, but only if the unstable manifold in one-dimensional. Because this method is more limited than the method using Lin vectors, we do not recommend it for normal usage.

To switch back to a normal homoclinic orbit, set $\text{ISTART}$ back to a positive value such as 1. Now HomCont has lost all the information about the adjoint, so if $\text{ITWIST}$ is set to 0, HomCont does a normal continuation without the adjoint, and if $\text{ITWIST}$ is set to 1, one needs to do a Newton dummy step first to recalculate the adjoint.

15.3.6 $\text{NREV}$, $\text{IREV}$

If $\text{NREV}=1$ then it is assumed that the system is reversible under the transformation $t \rightarrow -t$ and $U(i) \rightarrow -U(i)$ for all $i$ with $\text{IREV}(i)>0$. Then only half the homoclinic solution is solved for with right-hand boundary conditions specifying that the solution is symmetric under the reversibility (see Champneys & Spence (1993)). The number of free parameters is then reduced by one. Otherwise $\text{IREV}=0$.

15.3.7 $\text{NFIXED}$, $\text{IFIXED}$

Number and labels of test functions that are held fixed. E.g., with $\text{NFIXED}=1$ one can compute a locus in one extra parameter of a singularity defined by test function $\text{PSI}(\text{IFIXED}(1))=0$.

15.3.8 $\text{NPSI}$, $\text{IPSI}$

Number and labels of activated test functions for detecting homoclinic bifurcations, see Section 15.6 for a list. If a test function is activated then the corresponding parameter ($\text{IPSI}(I)+19$) must be added to the list of continuation parameters $\text{NICP},(\text{ICP}(I),I=1 \text{ NICP})$ and zero of this parameter added to the list of user-defined output points $\text{NUZR},(\text{/},I,\text{par}[1]),I=1, \text{NUZR}$ in c.xxx.

15.4 Restrictions on HomCont Constants.

Note that certain combinations of these constants are not allowed in the present implementation. In particular,

- The computation of orientation $\text{ITWIST}=1$ is not implemented for $\text{IEQUIB}<0$ (heteroclinic orbits), $\text{IEQUIB}=2$ (saddle-node homoclinics), $\text{IREV}=1$ (reversible systems), $\text{ISTART}=3$ (homotopy method for starting), or if the equilibrium contains complex eigenvalues in its linearization.

- The homotopy method $\text{ISTART}=3$ is not fully implemented for heteroclinic connections $\text{IEQUIB}<0$, saddle-node homoclinic orbits $\text{IEQUIB}=2$ or reversible systems $\text{IREV}=1$. 

141
Certain test functions are not valid for certain forms of continuation (see Section 15.6 below); for example PSI(13) and PSI(14) only make sense if ITWIST=1 and PSI(15) and PSI(16) only apply to IEQUIB=2.

15.5 Restrictions on the Use of par.

The parameters par[0] – par[8] can be used freely by the user. The other parameters are used as follows:

- par[10]: The value of par[10] equals the length of the time interval over which a homoclinic solution is computed. Also referred to as “period”. This must be specified in stpnt.

- par[9]: If ITWIST=1 then par[9] is used internally as a dummy parameter so that the adjoint equation is well-posed.

- par[11]–par[19]: These are used for specifying the equilibria and (if ISTART=3) the artificial parameters of the homotopy method (see Section 15.7 below).

- par[20]–par[35]: These parameters are used for storing the test functions (see Section 15.6).

The output is in an identical format to AUTO except that additional information at each computed point is written in fort.9. This information comprises the eigenvalues of the (left-hand) equilibrium, the values of each activated test function and, if ITWIST=1, whether the saddle homoclinic loop is orientable or not. Note that the statement about orientability is only meaningful if the leading eigenvalues are not complex and the homoclinic solution is not in a flip configuration, that is, none of the test functions \( \psi_i \) for \( i = 11, 12, 13, 14 \) is zero (or close to zero), see Section 15.6. Finally, the values of the NPSI activated test functions are written.

15.6 Test Functions.

Codimension-two homoclinic orbits are detected along branches of codim 1 homoclinics by locating zeroes of certain test functions \( \psi_i \). The test functions that are “switched on” during any continuation are given by the choice of the labels \( i \), and are specified by the parameters NPSI,(/,I,IPSI(I)),I=1,NPSI) in h.xxx. Here NPSI gives the number of activated test functions and IPSI(1),...,IPSI(NPSI) give the labels of the test functions (numbers between 1 and 16). A zero of each labeled test function defines a certain codimension-two homoclinic singularity, specified as follows. The notation used for eigenvalues is the same as that in Champneys & Kuznetsov (1994) or Champneys et al. (1996).

- \( i = 1 \): Resonant eigenvalues (neutral saddle); \( \mu_1 = -\lambda_1 \).

- \( i = 2 \): Double real leading stable eigenvalues (saddle to saddle-focus transition); \( \mu_1 = \mu_2 \).
- $i = 3$: Double real leading unstable eigenvalues (saddle to saddle-focus transition);
  $\lambda_1 = \lambda_2$.

- $i = 4$: Neutral saddle, saddle-focus or bi-focus (includes $i = 1$); $\Re(\mu_1) = -\Re(\lambda_1)$.

- $i = 5$: Neutrally-divergent saddle-focus (stable eigenvalues complex);
  $\Re(\lambda_1) = -\Re(\mu_1) - \Re(\mu_2)$.

- $i = 6$: Neutrally-divergent saddle-focus (unstable eigenvalues complex);
  $\Re(\mu_1) = -\Re(\lambda_1) - \Re(\lambda_2)$.

- $i = 7$: Three leading eigenvalues (stable); $\Re(\lambda_1) = -\Re(\mu_1) - \Re(\mu_2)$.

- $i = 8$: Three leading eigenvalues (unstable); $\Re(\mu_1) = -\Re(\lambda_1) - \Re(\lambda_2)$.

- $i = 9$: Local bifurcation (zero eigenvalue or Hopf): number of stable eigenvalues decreases;
  $\Re(\mu_1) = 0$.

- $i = 10$: Local bifurcation (zero eigenvalue or Hopf): number of unstable eigenvalues decreases;
  $\Re(\lambda_1) = 0$.

- $i = 11$: Orbit flip with respect to leading stable direction (e.g., 1D unstable manifold).

- $i = 12$: Orbit flip with respect to leading unstable direction, (e.g., 1D stable manifold).

- $i = 13$: Inclination flip with respect to stable manifold (e.g., 1D unstable manifold).

- $i = 14$: Inclination flip with respect to unstable manifold (e.g., 1D stable manifold).

- $i = 15$: Non-central homoclinic to saddle-node (in stable manifold).

- $i = 16$: Non-central homoclinic to saddle-node (in unstable manifold).

Expert users may wish to add their own test functions by editing the function `PSIHO` in `autlib5.c`.

It is important to remember that, in order to specify activated test functions, it is required to also add the corresponding label +20 to the list of continuation parameters and a zero of this parameter to the list of user-defined output points. Having done this, the corresponding parameters are output to the screen and zeros are accurately located.

### 15.7 Starting Strategies.

There are four possible starting procedures for continuation.

(i) Data can be read from a previously-obtained output point from AUTO (e.g., from continuation of a periodic orbit up to large period; note that if the end-point of the data stored is not close to the equilibrium, a phase shift must be performed by setting `ISTART=4`). These data can be read from fort.8 (saved to `s.xxx`) by making `IRS` correspond to the label of the data point in question.
(ii) Data from numerical integration (e.g., computation of a stable periodic orbit, or an approximate homoclinic obtained by shooting) can be read in from a data file using the general AUTO utility us (see earlier in the manual). The numerical data should be stored in a file xxx.dat, in multi-column format according to the read statement

\[
\text{READ(...,*) T(J), (U(I,J), I=1,NDIM)}
\]

where \( T \) runs in the interval \([0,1]\). After running us the restart data is stored in the format of a previously computed solution in s.dat. When starting from this solution IRS should be set to 1 and the value of ISTART is irrelevant.

(iii) By setting ISTART=2, an explicit homoclinic solution can be specified in the routine stpnt in the usual AUTO format, that is \( U = ... (T) \) where \( T \) is scaled to lie in the interval\([0,1]\).

(iv) The choice ISTART=3, allows for a homotopy method to be used to approach a homoclinic orbit starting from a small approximation to a solution to the linear problem in the unstable manifold (Doedel, Friedman & Monteiro 1993). For details of implementation, the reader is referred to Section 5.1.2. of Champneys & Kuznetsov (1994), under the simplification that we do not solve for the adjoint \( u(t) \) here. The basic idea is to start with a small solution in the unstable manifold, and perform continuation in \( \text{par}[10]=2T \) and dummy initial-condition parameters \( \xi_i \) in order to satisfy the correct right-hand boundary conditions, which are defined by zeros of other dummy parameters \( \omega_i \). More precisely, the left-hand end point is placed in the tangent space to the unstable manifold of the saddle and is characterized by NUNSTAB coordinates \( \xi_i \) satisfying the condition

\[
\xi_1^2 + \xi_2^2 + \ldots + \xi_{\text{NUNSTAB}}^2 = \epsilon_0^2,
\]

where \( \epsilon_0 \) is a user-defined small number. At the right-hand end point, NUNSTUB values \( \omega_i \) measure the deviation of this point from the tangent space to the stable manifold of the saddle.

Suppose that IEQUIB=0,1 and set IP=11+IEQUIB*NDIM. Then

\[
\begin{align*}
\text{par}[IP] & : \epsilon_0 \\
\text{par}[IP+i] & : \xi_i, \quad i=1,2,\ldots,\text{NUNSTAB} \\
\text{par}[IP+NUNSTAB+i] & : \omega_i, \quad i=1,2,\ldots,\text{NUNSTAB}
\end{align*}
\]

Note that to avoid interference with the test functions (i.e. \( \text{par}[20]\ldots\text{par}[35] \)), one must have IP+2*NUNSTAB < 21.

If an \( \omega_i \) is vanished, it can be frozen while another dummy or system parameter is allowed to vary in order to make consequently all \( \omega_i = 0 \). The resulting final solution gives the initial homoclinic orbit provided the right-hand end point is sufficiently close to the saddle. See Chapter 18 for an example, however, we recommend the homotopy method only for “expert users”.  

144
To compute the orientation of a homoclinic orbit (in order to detect inclination-flip bifurcations) it is necessary to compute, in tandem, a solution to the modified adjoint variational equation, by setting $\text{ITWIST}=1$. In order to obtain starting data for such a computation when restarting from a point where just the homoclinic is computed, upon increasing $\text{ITWIST}$ to 1, AUTO generates trivial data for the adjoint. Because the adjoint equations are linear, only a single step of Newton’s method is required to enable these trivial data to converge to the correct unique bounded solution. This can be achieved by making a single continuation step in a trivial parameter (i.e. a parameter that does not appear in the problem).

Decreasing $\text{ITWIST}$ to 0 automatically deletes the data for the adjoint from the continuation problem.

### 15.8 Notes on Running HomCont Demos.

HomCont demos are given in the following chapters. To copy all files of a demo $\text{xxx}$ (for example, $\text{san}$), move to a clean directory and type $\text{demo(\text{\textquote{xxx}})}$. Simply typing $\text{make}$ or $\text{make all}$ will then automatically execute all runs of the demo. At each step, the user is encouraged to plot the data saved by using the command $\text{plot}$ (e.g., $\text{plot(\text{\textquote{1}})}$ plots the data saved in $\text{b.1}$ and $\text{s.1}$).

Of course, in a real application, the runs will not have been prepared in advance, and AUTO-commands must be used. Such commands can be found in a table at the end of each chapter. A sequence of detailed AUTO-commands will be given in these tables as illustrated in Table 15.1 and Table 15.2 for two representative runs of HomCont demo $\text{san}$.

The user is encouraged to copy the format of one of these demos when constructing new examples.

The output of the HomCont demos reproduced in the following chapters is somewhat machine dependent, as already noted in Section 7.4. In exceptional circumstances, AUTO may reach its maximum number of steps $\text{NMX}$ before a certain output point, or the label of an output point may change. In such case the user may have to make appropriate changes in the AUTO constants-files.

Chapter 16

HomCont Demo : san.

16.1 Sandstede’s Model.

Consider the system (Sandstede 1995a)

\[
\begin{align*}
\dot{x} &= a x + b y - a x^2 + (\mu - \alpha z) x (2 - 3x) \\
\dot{y} &= b x + a y - \frac{3}{2} b x^2 - \frac{3}{2} a x y - (\mu - \alpha z) 2 y \\
\dot{z} &= c z + \mu x + \gamma x y + \alpha \beta (x^2 (1 - x) - y^2)
\end{align*}
\]  

(16.1)

as given in the file san.c. Choosing the constants appearing in (16.1) appropriately allows for computing inclination and orbit flips as well as non-orientable resonant bifurcations, see (Sandstede 1995a) for details and proofs. The starting point for all calculations is \(a = 0, b = 1\) where there exists an explicit solution given by

\[
(x(t), y(t), z(t)) = \left(1 - \left(\frac{1 - e^t}{1 + e^t}\right)^2, 4 e^t \left(1 - e^t\right) \frac{1 - e^t}{(1 + e^t)^3}, 0\right).
\]

This solution is specified in the routine stpnt.

16.2 Inclination Flip.

We start by copying the demo to the current work directory and running the first step

@dm san
make first

This computation starts from the analytic solution above with \(a = 0, b = 1, c = -2, \alpha = 0, \beta = 1\) and \(\gamma = \mu = \tilde{\mu} = 0\). The homoclinic solution is followed in the parameters \((a, \tilde{\mu}) = (\text{PAR}(1), \text{PAR}(8))\) up to \(a = 0.25\). The output is summarised on the screen as

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PAR(1)</th>
<th>L2-NORM</th>
<th>PAR(8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>EP</td>
<td>1</td>

<td>3</td>
<td>7.384434E-01</td>
<td>4.339575E-01</td>
<td>...</td>
</tr>
</tbody>
</table>
and saved in more detail as b.1, s.1 and d.1.

Next we want to add a solution to the adjoint equation to the solution obtained at \( a = 0.25 \).

This is achieved by making the change \( \text{ITWIST} = 1 \) saved in h.san.2, and \( \text{IRS} = 2, \ NMX = 2 \) and \( \text{ICP}(1) = 9 \) saved in c.san.2. We also disable any user-defined functions \( \text{NUZR} = 0 \). The computation so-defined is a single step in a trivial parameter \( \text{PAR}(9) \) (namely a parameter that does not appear in the problem). The effect is to perform a Newton step to enable AUTO to converge to a solution of the adjoint equation.

The output is stored in b.2, s.2 and d.2.

We can now continue the homoclinic plus adjoint in \((\alpha, \tilde{\mu}) = (\text{PAR}(4), \text{PAR}(8))\) by changing the constants (stored in c.san.3) to read \( \text{IRS} = 4, \ NMX = 50 \) and \( \text{ICP}(1) = 4 \). We also add \( \text{PAR}(10) \) to the list of continuation parameters \( \text{NICP}, (\text{ICP}(I), I = 1 \text{ NICP}) \). Here \( \text{PAR}(10) \) is a dummy parameter used in order to make the continuation of the adjoint well posed. Theoretically, it should be zero if the computation of the adjoint is successful (Sandstede 1995a). The test functions for detecting resonant bifurcations (\( \text{ISPI}(1) = 1 \)) and inclination flips (\( \text{ISPI}(1) = 13 \)) are also activated. Recall that this should be specified in three ways. First we add \( \text{PAR}(21) \) and \( \text{PAR}(33) \) to the list of continuation parameters in c.san.3, second we set up user defined output at zeros of these parameters in the same file, and finally we set \( \text{NPSI} = 2, (\text{ISPI}(1), \text{ISPI}(2)) = 1, 13 \) in h.san.3. We also add to c.san.3 another user zero for detecting when \( \text{PAR}(4) = 1.0 \). Running

make third

reads starting data from s.2 and outputs to the screen

<table>

</tr>
</tbody>
</table>

Full output is stored in b.3, s.3 and d.3. Note that the artificial parameter \( \epsilon = \text{PAR}(10) \) is zero within the allowed tolerance. At label 7, a zero of test function \( \psi_{13} \) has been detected which corresponds to an inclination flip with respect to the stable manifold. That the orientation of the homoclinic loop changes as the branch passes through this point can be read from the information in d.3. However in d.3, the line

\[ \text{ORIENTABLE} \ ( \ 0.2982090775D-03) \]

at \( \text{PT} = 35 \) would seem to contradict the detection of the inclination flip at this point. Nonetheless, the important fact is the zero of the test function; and note that the value of the variable indicating the orientation is small compared to its value at the other regular points. Data for the adjoint equation at \( \text{LAB} = 5, 7 \) and \( 9 \) at and on either side of the inclination flip are presented in Fig. 16.1. The switching of the solution between components of the leading unstable left eigenvector is apparent. Finally, we remark that the Newton step in the dummy parameter \( \text{PAR}(20) \) performed above is crucial to obtain convergence. Indeed, if instead we try to continue the homoclinic orbit and the solution of the adjoint equation directly by setting

147
(as saved in c.san.4) and running

\texttt{make fourth}

we obtain a no convergence error.

16.3 Non-orientable Resonant Eigenvalues.

Inspecting the output saved in the third run, we observe the existence of a non-orientable homoclinic orbit at label 7 corresponding to \texttt{N=40}. We restart at this label, with the first continuation parameter being once again \texttt{a = PAR(1)}, by changing constants and storing them in c.san.5 according to

\texttt{IRS = 7 DS = -0.05D0 NMX = 20 ICP(1) = 1}

Running,

\texttt{make fifth}

the output at label 10

\begin{verbatim}
   1 8 UZ 10 -1.304570E-07 ... 3.874816E-12 -1.468457E-09 -2.609139E-07
\end{verbatim}

indicates that AUTO has detected a zero of \texttt{PAR(21)}, implying that a non-orientable resonant bifurcation occurred at that point.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure16_1}
\caption{Second versus third component of the solution to the adjoint equation at labels 5, 7 and 9}
\end{figure}
In this section we compute an orbit flip. To this end we restart from the original explicit solution, without computing the orientation. We begin by separately performing continuation in $(\alpha, \tilde{\mu})$, $(\beta, \tilde{\mu})$, $(a, \tilde{\mu})$, $(b, \tilde{\mu})$ and $(\mu, \tilde{\mu})$ in order to reach the parameter values $(a, b, \alpha, \beta, \mu) = (0.5, 3, 1, 0, 0.25)$. The sequence of continuations up to the desired parameter values are run via

\[
\begin{align*}
&\text{make sixth} \\
&\text{make seventh} \\
&\text{make eighth} \\
&\text{make ninth} \\
&\text{make tenth}
\end{align*}
\]

with appropriate continuation parameters and user output values set in the corresponding files c.san.xx. All the output is saved to s.6.

The final saved point $\text{LAB}=10$ contains a homoclinic solution at the desired parameter values. From here we perform continuation in the negative direction of $(\mu, \tilde{\mu}) = (\text{PAR(7)}, \text{PAR(8)})$ with the test function $\psi_{11}$ for orbit flips with respect to the stable manifold activated.

\[
\begin{align*}
&\text{make eleventh}
\end{align*}
\]

The output detects an inclination flip (by a zero of $\text{PAR(31)}$) at $\text{PAR(7)}=0$

\[
\begin{align*}
\text{BR} & \quad \text{PT} & \quad \text{TY} & \quad \text{LAB} & \quad \text{PAR(7)} & \ldots & \quad \text{PAR(8)} & \quad \text{PAR(31)} \\
1 & \quad 5 & \quad \text{UZ} & \quad 12 & \quad 2.394737E-07 & \ldots & \quad 6.434492E-08 & \quad -4.133994E-06
\end{align*}
\]

at which parameter value the homoclinic orbit is contained in the $(x, y)$-plane (see Fig. 16.2).

Finally, we demonstrate that the orbit flip can be continued as three parameters $(\text{PAR(6)}, \text{PAR(7)}, \text{PAR(8)})$ are varied.

\[
\begin{align*}
&\text{make twelfth}
\end{align*}
\]
The orbit flip continues to be defined by a planar homoclinic orbit at \( \text{PAR(7)} = \text{PAR(8)} = 0 \).

Table 16.2: Detailed AUTO -Commands for running demo san.
Chapter 17

HomCont Demo : mtn.

17.1 A Predator-Prey Model with Immigration.

Consider the following system of two equations (Scheffer 1995)

\[
\begin{align*}
\dot{X} &= R X \left(1 - \frac{X}{K}\right) - \frac{A_1 X Y}{B_1 + X} + D_0 K \\ 
\dot{Y} &= E_1 \frac{A_1 X Y}{B_1 + X} - D_1 Y - \frac{A_2 Z Y^2}{B_2^2 + Y^2}.
\end{align*}
\] (17.1)

The values of all parameters except \((K, Z)\) are set as follows:

\[R = 0.5, \ A_1 = 0.4, \ B_1 = 0.6, \ D_0 = 0.01, \ E_1 = 0.6, \ A_2 = 1.0, \ B_2 = 0.5, \ D_1 = 0.15.\]

The parametric portrait of the system (17.1) on the \((Z, K)\)-plane is presented in Figure 17.1. It contains fold \((t_1, t_2)\) and Hopf \((H)\) bifurcation curves, as well as a homoclinic bifurcation curve \(P\). The fold curves meet at a cusp singular point \(C\), while the Hopf and the homoclinic curves originate at a Bogdanov-Takens point \(BT\). Only the homoclinic curve \(P\) will be considered here, the other bifurcation curves can be computed using AUTO or, for example, locbif (Khibnik, Kuznetsov, Levitin & Nikolaev 1993).

17.2 Continuation of Central Saddle-Node Homoclinics.

Local bifurcation analysis shows that at \(K = 6.0, \ Z = 0.06729762\ldots\), the system has a saddle-node equilibrium

\[(X^0, Y^0) = (5.738626\ldots, 0.5108401\ldots),\]

with one zero and one negative eigenvalue. Direct simulations reveal a homoclinic orbit to this saddle-node, departing and returning along its central direction (i.e., tangent to the null-vector).

Starting from this solution, stored in the file \texttt{mtn.dat}, we continue the saddle-node central homoclinic orbit with respect to the parameters \(K\) and \(Z\) by copying the demo and running it

\[@dm mtn make first\]
The file `mtn.c` contains approximate parameter values

\[ K = \text{PAR}(1) = 6.0, \ Z = \text{PAR}(2) = 0.06729762, \]

as well as the coordinates of the saddle-node

\[ X^0 = \text{PAR}(12) = 5.738626, \ Y^0 = \text{PAR}(13) = 0.5108401, \]

and the length of the truncated time-interval

\[ T_0 = \text{PAR}(11) = 1046.178. \]

Since a homoclinic orbit to a saddle-node is being followed, we have also made the choices

\[ \text{IEQUIB} = 2 \ \ \text{NUNSTAB} = 0 \ \ \text{NSTAB} = 1 \]

in `h.mtn.1`. The two test-functions, \( \psi_{15} \) and \( \psi_{16} \), to detect non-central saddle-node homoclinic orbits are also activated, which must be specified in three ways. Firstly, in `h.mtn.1`, NPSI is set to 2 and the active test functions \( \text{IPSI}(I), I=1,2 \) are chosen as 15 and 16. This sets up the monitoring of these test functions. Secondly, in `c.mtn.1` user-defined functions (NUZR=2) are set up to look for zeros of the parameters corresponding to these test functions. Recall that the parameters to be zeroed are always the test functions plus 20. Finally, these parameters are included in the list of continuation parameters (NICP, (ICP(I), I=1 NICP)).

Among the output there is a line

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PAR(1)</th>
<th>...</th>
<th>PAR(2)</th>
<th>PAR(35)</th>
<th>PAR(36)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>27</td>
<td>UZ</td>
<td>5</td>
<td>6.10437E+00</td>
<td>...</td>
<td>6.932475E-02</td>
<td>-6.782898E-07</td>
<td>8.203437E-02</td>
</tr>
</tbody>
</table>

indicating that a zero of the test function \( \text{IPSI}(1)=15 \) This means that at

\[ D_1 = (K^1, Z^1) = (6.6104\ldots, 0.069325\ldots) \]

the homoclinic orbit to the saddle-node becomes non-central, namely, it returns to the equilibrium along the stable eigenvector, forming a non-smooth loop. The output is saved in `b.1`, `s.1` and `d.1`. Repeating computations in the opposite direction along the curve, IRS=1, DS=-0.01 in `c.mtn.2`,

\[ \text{make second} \]

one obtains

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PAR(1)</th>
<th>...</th>
<th>PAR(2)</th>
<th>PAR(35)</th>
<th>PAR(36)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>34</td>
<td>UZ</td>
<td>9</td>
<td>5.180323E+00</td>
<td>...</td>
<td>6.385506E-02</td>
<td>3.349720E-09</td>
<td>9.361957E-02</td>
</tr>
</tbody>
</table>

which means another non-central saddle-node homoclinic bifurcation occurs at

\[ D_2 = (K^2, Z^2) = (5.1803\ldots, 0.063855\ldots). \]

Note that these data were obtained using a smaller value of NTST than the original computation (compare `c.mtn.1` with `c.mtn.2`). The high original value of NTST was only necessary for the first few steps because the original solution is specified on a uniform mesh.
17.3 Switching between Saddle-Node and Saddle Homoclinic Orbits.

Now we can switch to continuation of saddle homoclinic orbits at the located codim 2 points $D_1$ and $D_2$.

\textit{make third}

starts from $D_1$. Note that now

\[
\text{NUNSTAB} = 1 \quad \text{IEQUIB} = 1
\]

has been specified in \texttt{h.mtn.3}. Also, test functions $\psi_9$ and $\psi_{10}$ have been activated in order to monitor for non-hyperbolic equilibria along the homoclinic locus. We get the following output

\begin{verbatim}
BR PT TY LAB PAR(1) ... PAR(2) PAR(29) PAR(30)
1 10 11 7.114523E+00 ... 7.081751E-02 -4.649861E-01 3.183429E-03
1 20 12 9.176810E+00 ... 7.678731E-02 -4.684912E-01 1.609294E-02
1 30 13 1.210834E+01 ... 8.543468E-02 -4.718871E-01 3.069638E-02
1 40 EP 14 1.503788E+01 ... 9.428036E-02 -4.743794E-01 4.144558E-02
\end{verbatim}

The fact that PAR(29) and PAR(30) do not change sign indicates that there are no further non-hyperbolic equilibria along this branch. Note that restarting in the opposite direction with IRS=11, DS=-0.02

\textit{make fourth}

will detect the same codim 2 point $D_1$ but now as a zero of the test-function $\psi_{10}$

\begin{verbatim}
BR PT TY LAB PAR(1) ... PAR(2) PAR(29) PAR(30)
1 10 UZ 15 6.610459E+00 ... 6.932482E-02 -4.636603E-01 1.725013E-09
\end{verbatim}

Note that the values of PAR(1) and PAR(2) differ from that at label 4 only in the sixth significant figure.

Actually, the program runs further and eventually computes the point $D_2$ and the whole lower branch of $P$ emanating from it, however, the solutions between $D_1$ and $D_2$ should be considered as spurious\(^\dagger\), therefore we do not save these data. The reliable way to compute the lower branch of $P$ is to restart computation of saddle homoclinic orbits in the other direction from the point $D_2$.

\textit{make fifth}

This gives the lower branch of $P$ approaching the BT point (see Figure 17.1)

\(^\dagger\) The program actually computes the saddle-saddle heteroclinic orbit bifurcating from the non-central saddle-node homoclinic at the point $D_1$, see Champneys et al. (1996, Fig. 2), and continues it to the one emanating from $D_2$. 

155
The data are appended to the stored results in b.1, s.1 and d.1. One could now display all data using the AUTO command @p 1 to reproduce the curve $P$ shown in Figure 17.1.

It is worthwhile to compare the homoclinic curves computed above with a curve $T_0 = \text{const}$ along which the system has a limit cycle of constant large period $T_0 = 1046.178$, which can easily be computed using AUTO or locbif. Such a curve is plotted in Figure 17.2. It obviously approximates well the saddle homoclinic loci of $P$, but demonstrates much bigger deviation from the saddle-node homoclinic segment $D_1D_2$. This happens because the period of the limit cycle grows to infinity while approaching both types of homoclinic orbit, but with different asymptotics: as $-\ln \|\alpha - \alpha^*\|$, in the saddle homoclinic case, and as $\|\alpha - \alpha^*\|^{-1}$ in the saddle-node case.

### 17.4 Three-Parameter Continuation.

Finally, we can follow the curve of non-central saddle-node homoclinic orbits in three parameters. The extra continuation parameter is $D_0 = \text{PAR}(3)$. To achieve this we restart at label 4, corresponding to the codim 2 point $D_1$. We return to continuation of saddle-node homoclinics, $\text{NUNSTAB}=0, \text{IEQUIB}=2$, but append the defining equation $\psi_{15} = 0$ to the continuation problem (via $\text{NFIXED}=1, \text{IFIXED}(1)=15$). The new continuation problem is specified in c.mtn.6 and h.mtn.6.

Notice that we set $\text{ILP}=1$ and choose $\text{PAR}(3)$ as the first continuation parameter so that AUTO can detect limit points with respect to this parameter. We also make a user-defined function ($\text{NUZR}=1$) to detect intersections with the plane $D_0 = 0.01$. We get among other output

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PAR(1)</th>
<th>...</th>
<th>PAR(2)</th>
<th>PAR(29)</th>
<th>PAR(30)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>22</td>
<td>LP</td>
<td>19</td>
<td>1.081212E-02</td>
<td>5.325894E+00</td>
<td>5.673631E+00</td>
<td>6.608184E-02</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>31</td>
<td>UZ</td>
<td>20</td>
<td>1.000000E-02</td>
<td>4.819681E+00</td>
<td>5.180317E+00</td>
<td>6.385503E-02</td>
<td></td>
</tr>
</tbody>
</table>

the first line of which represents the $D_0$ value at which the homoclinic curve $P$ has a tangency with the branch $t_2$ of fold bifurcations. Beyond this value of $D_0$, $P$ consists entirely of saddle homoclinic orbits. The data at label 20 reproduce the coordinates of the point $D_2$. The results of this computation and a similar one starting from $D_1$ in the opposite direction (with $\text{DS}=-0.01$) are displayed in Figure 17.3.
### 17.5 Detailed AUTO-Commands.

<table>

Chapter 18

HomCont Demo : kpr.

18.1 Koper’s Extended Van der Pol Model.

The equation-file kpr.c contains the equations

\[
\begin{align*}
\dot{x} &= \epsilon_1 (ky - x^3 + 3x - \lambda) \\
\dot{y} &= x - 2y + z \\
\dot{z} &= \epsilon_2 (y - z),
\end{align*}
\]

(18.1)

with \( \epsilon_1 = 0.1 \) and \( \epsilon_2 = 1 \) (Koper 1995).

To copy across the demo kpr and compile we type

```
@dm kpr
```

18.2 The Primary Branch of Homoclinics.

First, we locate a homoclinic orbit using the homotopy method. The file kpr.c already contains approximate parameter values for a homoclinic orbit, namely \( \lambda = \text{PAR}(1) = -1.851185 \), \( k = \text{PAR}(2) = -0.15 \). The files c.kpr.1 and h.kpr.1 specify the appropriate constants for continuation in \( 2T = \text{PAR}(11) \) (also referred to as PERIOD) and the dummy parameter \( \omega_1 = \text{PAR}(17) \) starting from a small solution in the local unstable manifold;

```
make first
```

Among the output there is the line

```
BR PT TY LAB PERIOD L2-NORM ... PAR(17) ...
1 29 UZ 2 1.900184E+01 1.693817E+00 ... 4.433433E-09 ...
```

which indicates that a zero of the artificial parameter \( \omega_1 \) has been located. This means that the right-hand end point of the solution belongs to the plane that is tangent to the stable manifold at the saddle. The output is stored in files b.1, s.1, d.1. Upon plotting the data at label 2 (see Figure 18.1) it can be noted that although the right-hand projection boundary condition is satisfied, the solution is still quite away from the equilibrium.
Figure 18.1: Projection on the \((x, y)\)-plane of solutions of the boundary value problem with 
\(2T = 19.08778\).

Figure 18.2: Projection on the \((x, y)\)-plane of solutions of the boundary value problem with 
\(2T = 60.0\).
The right-hand endpoint can be made to approach the equilibrium by performing a further continuation in $T$ with the right-hand projection condition satisfied ($\text{PAR}(17)$ fixed) but with $\lambda$ allowed to vary.

make second

the output at label 4, stored in $kpr.2$,

<table>
<thead>
<tr>
<th>BR</th>

<td>1.672806E+00</td>
<td>...</td>
<td>-1.851185E+00</td>
<td>...</td>
</tr>
</tbody>
</table>

provides a good approximation to a homoclinic solution (see Figure 18.2).

The second stage to obtain a starting solution is to add a solution to the modified adjoint variational equation. This is achieved by setting both $\text{ITWIST}$ and $\text{ISTART}$ to 1 (in $h.kpr.3$), which generates a trivial guess for the adjoint equations. Because the adjoint equations are linear, only a single Newton step (by continuation in a trivial parameter) is required to provide a solution. Rather than choose a parameter that might be used internally by AUTO, in $c.kpr.3$ we take the continuation parameter to be $\text{PAR}(11)$, which is not quite a trivial parameter but whose affect upon the solution is mild.

make third

The output at the second point (label 6) contains the converged homoclinic solution (variables ($U(1)$, $U(2)$, $U(3)$) and the adjoint ($U(4)$, $U(5)$, $U(6)$)). We now have a starting solution and are ready to perform two-parameter continuation.

The fourth run

make fourth

continues the homoclinic orbit in $\text{PAR}(1)$ and $\text{PAR}(2)$. Note that several other parameters appear in the output. $\text{PAR}(10)$ is a dummy parameter that should be zero when the adjoint is being computed correctly; $\text{PAR}(29)$, $\text{PAR}(30)$, $\text{PAR}(33)$ correspond to the test functions $\psi_9$, $\psi_{10}$, and $\psi_{13}$. That these test functions were activated is specified in three places in $c.kpr.4$ and $h.kpr.4$ as described in Section 15.6.

Note that at the end-point of the branch (reached when after $\text{NMX}=50$ steps) $\text{PAR}(29)$ is approximately zero which corresponds to a zero of $\psi_9$, a non-central saddle-node homoclinic orbit. We shall return to the computation of this codimension-two point later. Before reaching this point, among the output we find two zeroes of $\text{PAR}(33)$ (test function $\psi_{13}$) which gives the accurate location of two inclination-flip bifurcations,

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>

<th>PAR(2)</th>
<th>...</th>
<th>PAR(10)</th>
<th>...</th>
<th>PAR(33)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>6</td>
<td>UZ</td>
<td>10</td>
<td>-1.801662E+00</td>
<td>...</td>
<td>-2.002660E-01</td>
<td>...</td>
<td>-7.255434E-07</td>
<td>...</td>
<td>-1.425714E-04</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>UZ</td>
<td>11</td>
<td>-1.568756E+00</td>
<td>...</td>
<td>-4.395468E-01</td>
<td>...</td>
<td>-2.156353E-07</td>
<td>...</td>
<td>4.514073E-07</td>
</tr>
</tbody>
</table>

That the test function really does have a regular zero at this point can be checked from the data saved in $b.3$, plotting $\text{PAR}(33)$ as a function of $\text{PAR}(1)$ or $\text{PAR}(2)$. Figure 18.3 presents solutions $\phi(t)$ of the modified adjoint variational equation (for details see Champneys et al. (1996)) at parameter values on the homoclinic branch before and after the first detected inclination
Figure 18.3: Projection on the $(x,y)$-plane of solutions $\phi(t)$ at 1 ($\lambda = -1.825470, k = -0.1760749$) and 2 ($\lambda = -1.686154, k = -0.3183548$).

Figure 18.4: Three-dimensional blow-up of the solution curves $\phi(t)$ at labels 1 (dotted) and 2 (solid line) from Figure 3.8.
Figure 18.5: Computed homoclinic orbits approaching the BT point

Continuing in the other direction

we approach a Bogdanov-Takens point

```
BR  PT  TY  LAB    PAR(1) ... PAR(10) ... PAR(33)
 1  50  EP  13  -1.938276E+00 ... -7.523344E+00 ... 6.310810E+01
```

Note that the numerical approximation has ceased to become reliable, since \( \text{PAR}(10) \) has now become large. Phase portraits of homoclinic orbits between the BT point and the first inclination flip are depicted in Figure 18.5. Note how the computed homoclinic orbits approaching the BT point have their endpoints well away from the equilibrium. To follow the homoclinic orbit to the BT point with more precision, we would need to first perform continuation in \( T(\text{PAR}(11)) \) to obtain a more accurate homoclinic solution.

### 18.3 More Accuracy and Saddle-Node Homoclinic Orbits.

Continuation in \( T \) in order to obtain an approximation of the homoclinic orbit over a longer interval is necessary for parameter values near a non-hyperbolic equilibrium (either a saddle-node or BT) where the convergence to the equilibrium is slower. First, we start from the original homoclinic orbit computed via the homotopy method, label 4, which is well away from the non-hyperbolic equilibrium. Also, we shall no longer be interested in in inclination flips so we set \( \text{ITWIST}=0 \) in \( \text{c.kpr.6} \), and in order to compute up to \( \text{PAR}(11)=1000 \), we set up a user-defined function for this. Running AUTO with \( \text{PAR}(11) \) and \( \text{PAR}(2) \) as free parameters

```
```
we obtain among the output

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PERIOD</th>
<th>L2-NORM</th>
<th>...</th>
<th>PAR(2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>35</td>
<td>UZ</td>
<td>6</td>
<td>1.000000E+03</td>
<td>1.661910E+00</td>
<td>...</td>
<td>-1.500000E-01</td>
</tr>
</tbody>
</table>

We can now repeat the computation of the branch of saddle homoclinic orbits in PAR(1) and PAR(2) from this point with the test functions $\psi_9$ and $\psi_{10}$ for non-central saddle-node homoclinic orbits activated

*make seventh*

The saddle-node point is now detected at

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PAR(1)</th>
<th>...</th>
<th>PAR(2)</th>
<th>PAR(29)</th>
<th>PAR(30)</th>
</tr>
</thead>
<tbody>
<tr>

<td>30</td>
<td>UZ</td>
<td>8</td>
<td>1.765003E-01</td>
<td>...</td>
<td>-2.405345E+00</td>
<td>2.743361E-06</td>
<td>2.309317E+01</td>
</tr>
</tbody>
</table>

which is stored in s.7. That PAR(29) ($\psi_9$) is zeroed shows that this is a non-central saddle-node connecting the centre manifold to the strong stable manifold. Note that all output beyond this point, although a well-posed solution to the boundary-value problem, is spurious in that it no longer represents a homoclinic orbit to a saddle equilibrium (see Champneys et al. (1996)). If we had chosen to, we could continue in the other direction in order to approach the BT point more accurately by reversing the sign of DS in c.kpr.7.

The files c.kpr.9 and h.kpr.9 contain the constants necessary for switching to continuation of the central saddle-node homoclinic curve in two parameters starting from the non-central saddle-node homoclinic orbit stored as label 8 in s.7.

*make eighth*

In this run we have activated the test functions for saddle to saddle-node transition points along curves of saddle homoclinic orbits ($\psi_{15}$ and $\psi_{16}$). Among the output we find

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PAR(1)</th>
<th>...</th>
<th>PAR(2)</th>
<th>PAR(35)</th>
<th>PAR(36)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>38</td>
<td>UZ</td>
<td>13</td>
<td>1.765274E-01</td>
<td>...</td>
<td>-2.405284E+00</td>
<td>9.705426E-03</td>
<td>-5.464784E-07</td>
</tr>
</tbody>
</table>

which corresponds to the branch of homoclinic orbits leaving the locus of saddle-nodes in a second non-central saddle-node homoclinic bifurcation (a zero of $\psi_{16}$).

Note that the parameter values do not vary much between the two codimension-two non-central saddle-node points (labels 8 and 13). However, Figure 18.6 shows clearly that between the two codimension-two points the homoclinic orbit rotates between the two components of the 1D stable manifold, i.e. between the two boundaries of the center-stable manifold of the saddle node. The overall effect of this process is the transformation of a nearby “small” saddle homoclinic orbit to a “big” saddle homoclinic orbit (i.e. with two extra turning points in phase space).

Finally, we can switch to continuation of the big saddle homoclinic orbit from the new codим 2 point at label 13.

*make ninth*

Note that AUTO takes a large number of steps near the line PAR(1)=0, while PAR(2) approaches $-2.189\ldots$ (which is why we chose such a large value NMX=500 in c.kpr.9). This particular computation ends at
Figure 18.6: Two non-central saddle-node homoclinic orbits, 1 and 3; and, 2, a central saddle-node homoclinic orbit between these two points

Figure 18.7: The big homoclinic orbit approaching a figure-of-eight
By plotting phase portraits of orbits approaching this end point (see Figure 18.7) we see a “canard-like” like transformation of the big homoclinic orbit to a pair of homoclinic orbits in a figure-of-eight configuration. That we get a figure-of-eight is not a surprise because \( \text{PAR}(1)=0 \) corresponds to a symmetry in the differential equations (Koper 1994); note also that the equilibrium, stored as \( \text{( PAR}(12) , \text{ PAR}(13) , \text{ PAR}(14) ) \) in \text{d.9} , approaches the origin as we approach the figure-of-eight homoclinic.

### 18.4 Three-Parameter Continuation.

We now consider curves in three parameters of each of the codimension-two points encountered in this model, by freeing the parameter \( \epsilon = \text{PAR}(3) \). First we continue the first inclination flip stored at label 7 in \text{s.3}

\[
\text{make tenth}
\]

Note that \( \text{ITWIST}=1 \) in \text{h.kpr.10} , so that the adjoint is also continued, and there is one fixed condition \( \text{IFIXED}(1)=13 \) so that test function \( \psi_{13} \) has been frozen. Among the output there is a codimension-three point (zero of \( \psi_{9} \)) where the neutrally twisted homoclinic orbit collides with the saddle-node curve

\[
\text{BR PT TY LAB PAR}(1) \ldots \text{PAR}(2) \text{PAR}(3) \text{PAR}(29) \ldots
\]

1 28 UZ 14 1.282702E-01 \ldots -2.519325E+00 5.744770E-01 -4.347113E-09 \ldots

The other detected inclination flip (at label 8 in \text{s.3}) is continued similarly

\[
\text{make eleventh}
\]

giving among its output another codim 3 saddle-node inclination-flip point

\[
\text{BR PT TY LAB PAR}(1) \ldots \text{PAR}(2) \text{PAR}(3) \text{PAR}(29) \ldots
\]

1 27 UZ 14 1.535420E-01 \ldots -2.458100E+00 1.171705E+00 -1.933188E-07 \ldots

Output beyond both of these codim 3 points is spurious and both computations end in an MX point (no convergence).

To continue the non-central saddle-node homoclinic orbits it is necessary to work on the data without the solution \( \phi(t) \). We restart from the data saved at \text{LAB}=8 and \text{LAB}=13 in \text{s.7} and \text{s.8} respectively. We could continue these codim 2 points in two ways, either by appending the defining condition \( \psi_{16} = 0 \) to the continuation of saddle-node homoclinic orbits (with \( \text{IEQUIB}=2 \), etc.), or by appending \( \psi_{9} = 0 \) to the continuation of a saddle homoclinic orbit (with \( \text{IEQUIB}=1 \). The first approach is used in the example \text{mtn} , for contrast we shall adopt the second approach here.

\[
\text{make twelfth}
\]

\[
\text{make thirteenth}
\]

The projection onto the \((\epsilon, k)\)-plane of all four of these codimension-two curves is given in Figure 18.8. The intersection of the inclination-flip lines with one of the non-central saddle-node homoclinic lines is apparent. Note that the two non-central saddle-node homoclinic orbit curves are almost overlaid, but that as in Figure 18.6 the orbits look quite distinct in phase space.
### 18.5 Detailed AUTO -Commands.

Table 18.2: Detailed AUTO-Commands for running demo $kpr$. 

169
Chapter 19

HomCont Demo : cir.

19.1 Electronic Circuit of Freire et al.

Consider the following model of a three-variable electronic circuit (Freire, Rodríguez-Luis, Gamero & Ponce 1993)

\[
\begin{align*}
\dot{x} &= \frac{[-(\beta + \nu)x + \beta y - a_3 x^3 + b_3 (y - x)^3]}{r}, \\
\dot{y} &= \beta x - (\beta + \gamma) y - z - b_3 (y - x)^3, \\
\dot{z} &= y.
\end{align*}
\]

(19.1)

These autonomous equations are also considered in the AUTO demo tor.

First, we copy the demo into a new directory and compile

```
@dm cir
```

The system is contained in the equation-file `cir.c` and the initial run-time constants are stored in `c.cir.1` and `h.cir.1`. We begin by starting from the data from `cir.dat` for a saddle-focus homoclinic orbit at \( \nu = -0.721309, \beta = 0.6, \gamma = 0, \), \( r = 0.6, A_3 = 0.328578 \) and \( B_3 = 0.933578 \), which was obtained by shooting over the time interval \( 2T = PAR(11) = 36.13 \). We wish to follow the branch in the \((\beta, \nu)\)-plane, but first we perform continuation in \((T, \nu)\) to obtain a better approximation to a homoclinic orbit.

```
make first
```

yields the output

<table>
<thead>
<tr>
<th>BR</th>

</tr>
</tbody>
</table>

Note that \( \nu = PAR(1) \) remains constant during the continuation as the parameter values do not change, only the the length of the interval over which the approximate homoclinic solution is computed. Note from the eigenvalues, stored in `d.1` that this is a homoclinic orbit to a saddle-focus with a one-dimensional unstable manifold.

We now restart at \( LAB=3 \), corresponding to a time interval \( 2T = 200 \), and change the principal continuation parameters to be \((\nu, \beta)\). The new constants defining the continuation are given in
c.cir.2 and h.cir.2. We also activate the test functions pertinent to codimension-two singularities which may be encountered along a branch of saddle-focus homoclinic orbits, viz. $\psi_2, \psi_4, \psi_5, \psi_9$ and $\psi_{10}$. This must be specified in three ways: by choosing NPSI=5 and appropriate IPSI(I) in h.cir.2, by adding the corresponding parameter labels to the list of continuation parameters ICP(I) in c.cir.2 (recall that these parameter indices are 20 more than the corresponding $\psi$ indices), and finally adding USZR functions defining zeros of these parameters in c.cir.2. Running

\texttt{make second}

results in

</table>

with results saved in b.2, s.2, d.2. Upon inspection of the output, note that label 5, where PAR(25)$\approx 0$, corresponds to a neutrally-divergent saddle-focus, $\psi_5 = 0$. Label 7, where PAR(29)$\approx 0$ corresponds to a local bifurcation, $\psi_9 = 0$, which we note from the eigenvalues stored in d.2 corresponds to a \textit{Shil’nikov-Hopf} bifurcation. Note that PAR(2) is also approximately zero at label 7, which accords with the analytical observation that the origin of (19.1) undergoes a Hopf bifurcation when $\beta = 0$. Labels 6 and 8 are the user-defined output points, the solutions at which are plotted in Fig. 19.1. Note that solutions beyond label 7 (e.g., the plotted solution at label 8) do not correspond to homoclinic orbits, but to \textit{point-to-cycle} heteroclinic orbits (c.f. Section 2.2.1 of Champneys et al. (1996)).

We now continue in the other direction along the branch. It turns out that starting from the initial point in the other direction results in missing a codim 2 point which is close to the starting point. Instead we start from the first saved point from the previous computation (label 5 in s.2):

\texttt{make third}

contains a neutral saddle-focus (a \textit{Belyakov} transition) at LAB=10 ($\psi_4 = 0$), a double real leading eigenvalue (saddle-focus to saddle transition) at LAB =11 ($\psi_2 = 0$) and a neutral saddle at LAB=12 ($\psi_1 = 0$). Data at several points on the complete branch are plotted in Fig. 19.2. If we had continued further (by increasing NMX), the computation would end at a no convergence error TY=MX owing to the homoclinic branch approaching a Bogdanov-Takens singularity at small amplitude. To compute further towards the BT point we would first need to continue to a higher value of PAR(11).

Chapter 20

HomCont Demo : she.

20.1 A Heteroclinic Example.

The following system of five equations Rucklidge & Mathews (1995)

\[
\begin{align*}
\dot{x} &= \mu x + x y - z u, \\
\dot{y} &= -y - x^2, \\
\dot{z} &= (4\sigma x u + 4\sigma \mu z - 9\sigma z + 4x u + 4\mu z)/4(1 + \sigma) \\
\dot{u} &= -\sigma u/4 - \sigma Qv/4\pi^2 + 3(1 + \sigma)zx/4\sigma \\
\dot{v} &= \zeta u/4 - \zeta v/4
\end{align*}
\] (20.1)

has been used to describe shearing instabilities in fluid convection. The equations possess a rich structure of local and global bifurcations. Here we shall reproduce a single curve in the \((\sigma, \mu)\)-plane of codimension-one heteroclinic orbits connecting a non-trivial equilibrium to the origin for \(Q = 0\) and \(\zeta = 4\). The defining problem is contained in equation-file she.c\(^1\), and starting data for the orbit at \((\sigma, \mu) = (0.5, 0.163875)\) are stored in she.dat, with a truncation interval of \(\text{PAR(11)} = 85.07\).

We begin by computing towards \(\mu = 0\) with the option \text{IEQUIB}=-2 which means that both equilibria are solved for as part of the continuation process.

\[
\text{@dm she} \\
\text{make first}
\]

This yields the output

\[
\begin{array}{cccccccc}
\text{BR} & \text{PT} & \text{TY} & \text{LAB} & \text{PAR(3)} & \text{L2-NORM} & \ldots & \text{PAR(1)} \\
1 & 5 & 2 & 4.528332E-01 & 3.726787E-01 & \ldots & 1.364973E-01 \\
1 & 10 & 3 & 3.943370E-01 & 3.303798E-01 & \ldots & 1.044119E-01 \\
1 & 15 & 4 & 3.358942E-01 & 2.873213E-01 & \ldots & 7.515570E-02 \\
1 & 20 & 5 & 2.772726E-01 & 2.433403E-01 & \ldots & 4.952636E-02 \\
1 & 25 & 6 & 2.181955E-01 & 1.981358E-01 & \ldots & 2.845849E-02 \\
1 & 30 & \text{EP} & 7 & 1.581633E-01 & 1.512340E-01 & \ldots & 1.292975E-02
\end{array}
\]

\(^1\)The last parameter used to store the equilibria (\text{PAR(21)}) is overlaped here with the first test-function. In this example, it is harmless since the test functions are irrelevant for heteroclinic continuation.
Alternatively, for this problem there exists an analytic expression for the two equilibria. This is specified in the subroutine `pvls` of `she.c`. Re-running with `IEQUIB=-1`

we obtain the output

```
BR PT TY LAB PAR(3) L2-NORM ... PAR(1)
1  5  2  4.432015E-01  3.657716E-01 ...  1.310559E-01
1 10  3  3.723085E-01  3.142439E-01 ...  9.300982E-02
1 15  4  3.00842E-01  2.611556E-01 ...  5.93966E-02
1 20  5  2.286652E-01  2.062194E-01 ...  3.17939E-02
1 25  6  1.555409E-01  1.491652E-01 ...  1.23989E-02
1 30  EP 7  8.107462E-02  9.143108E-02 ...  2.38661E-03
```

This output is similar to that above, but note that it is obtained slightly more efficiently because the extra parameters `PAR(12-21)` representing the coordinates of the equilibria are no longer part of the continuation problem. Also note that AUTO has chosen to take slightly larger steps along the branch. Finally, we can continue in the opposite direction along the branch from the original starting point (again with `IEQUIB=-1`).

```
make third
```

```
BR PT TY LAB PAR(3) L2-NORM ... PAR(1)
1  5  8  4.997590E-01  4.060153E-01 ...  1.637322E-01
1 10  9  5.705299E-01  4.551872E-01 ...  2.065264E-01
1 15 10  6.416439E-01  5.031844E-01 ...  2.507829E-01
1 20 11  7.133301E-01  5.500668E-01 ...  2.959336E-01
1 25 12  7.857688E-01  5.958712E-01 ...  3.415492E-01
1 30 13  8.590970E-01  6.406182E-01 ...  3.872997E-01
1 35  EP 14  9.334159E-01  6.843173E-01 ...  4.329270E-01
```

The results of both computations are presented in Figure 20.1, from which we see that the orbit shrinks to zero as `PAR(1)=\mu \to 0`.

```
Figure 20.1: Projections into \((x, y, z)\)-space of the family of heteroclinic orbits.

Table 20.1: Detailed AUTO -Commands for running demo she.
Chapter 21

HomCont Demo: rev.

21.1 A Reversible System.

The fourth-order differential equation

\[ u'''' + Pu'' + u - u^3 = 0 \]

arises in a number of contexts, e.g., as the travelling-wave equation for a nonlinear-Schrödinger equation with fourth-order dissipation (Buryak & Akhmediev 1995) and as a model of a strut on a symmetric nonlinear elastic foundation (Hunt, Bolt & Thompson 1989). It may be expressed as a system

\[
\begin{align*}
    \dot{u}_1 &= u_2 \\
    \dot{u}_2 &= u_3 \\
    \dot{u}_3 &= u_4 \\
    \dot{u}_4 &= -Pu_3 - u_1 + u_1^3
\end{align*}
\]  

(21.1)

Note that (21.1) is invariant under two separate reversibilities

\[ R_1: (u_1, u_2, u_3, u_4, t) \mapsto (u_1, -u_2, u_3, -u_4, -t) \]  

(21.2)

and

\[ R_2: (u_1, u_2, u_3, u_4, t) \mapsto (-u_1, u_2, -u_3, u_4, -t) \]  

(21.3)

First, we copy the demo into a new directory

```
@dm rev
```

For this example, we shall make two separate starts from data stored in equation and data files `rev.c.1`, `rev.dat.1` and `rev.c.3`, `rev.dat.3` respectively. The first of these contains initial data for a solution that is reversible under \( R_1 \) and the second for data that is reversible under \( R_2 \).

21.2 An \( R_1 \)-Reversible Homoclinic Solution.

The first run

```
make first
```

177
starts by copying the files \texttt{rev.c.1} and \texttt{rev.dat.1} to \texttt{rev.c} and \texttt{rev.dat}. The orbit contained in the data file is a “primary” homoclinic solution for \( P = 1.6 \), with truncation (half-)interval \( \text{PAR}(11) = 39.048429 \). which is reversible under \( R_1 \). Note that this reversibility is specified in \texttt{h.rev.1} via \texttt{NREV=1}, \( \text{(IREV(I), I=1,NDIM)} = 0 \ 1 \ 0 \ 1 \). Note also, from \texttt{c.rev.1} that we only have one free parameter \( \text{PAR}(1) \) because symmetric homoclinic orbits in reversible systems are generic rather than of codimension one. The first run results in the output

\begin{verbatim}
BR  PT  TY  LAB  PAR(1)   L2-NORM  MAX U(1) ... \\
1  7  UZ  2  1.700002E+00  2.633353E-01  4.179794E-01 ... \\
1 12  UZ  3  1.800000E+00  2.682659E-01  4.806063E-01 ... \\
1 15  UZ  4  1.900006E+00  2.493415E-01  4.429364E-01 ... \\
1 20  EP  5  1.996247E+00  1.111306E-01  1.007111E-01 ... \\
\end{verbatim}

which is consistent with the theoretical result that the solution tends uniformly to zero as \( P \to 0 \). Note, by plotting the data saved in \texttt{s.1} that only “half” of the homoclinic orbit is computed up to its point of symmetry. See Figure 21.1.

The second run continues in the other direction of \( \text{PAR}(1) \), with the test function \( \psi_2 \) activated for the detection of saddle to saddle-focus transition points

\begin{verbatim}
make second
\end{verbatim}

The output

\begin{verbatim}
BR  PT  TY  LAB  PAR(1)   L2-NORM  MAX U(1) ...  PAR(22) \\
1 11  UZ  6  1.000005E+00  2.555446E-01  1.767149E-01 ... -3.000005E+00 \\
1 22  UZ  7  -1.198325E-07  2.625491E-01  4.697314E-02 ... -2.000000E+00 \\
1 33  UZ  8  -2.000000E+00  2.873838E-01  1.245735E-11 ...  2.318248E-08 \\
1 44  UZ  9  -3.099341E+00  3.020172E-01 -2.749454E-11 ...  1.099341E+00 \\
1 55  EP 10  -3.099341E+00  3.020172E-01 -2.749454E-11 ...  1.099341E+00 \\
\end{verbatim}

shows a saddle to saddle-focus transition (indicated by a zero of \( \text{PAR}(22) \)) at \( \text{PAR}(1)=-2 \). Beyond that label the first component of the solution is negative and (up to the point of symmetry) monotone decreasing. See Figure 21.2.

\subsection{An \textit{R2}-Reversible Homoclinic Solution.}

\begin{verbatim}
make third
\end{verbatim}

Copies the files \texttt{rev.c.3} and \texttt{rev.dat.3} to \texttt{rev.c} and \texttt{rev.dat}, and runs them with the constants stored in \texttt{c.rev.3} and \texttt{h.rev.3}. The orbit contained in the data file is a “multi-pulse” homoclinic solution for \( P = 1.6 \), with truncation (half-)interval \( \text{PAR}(11) = 47.4464189 \). which is reversible under \( R_2 \). This reversibility is specified in \texttt{h.rev.1} via \texttt{NREV=1}, \( \text{(IREV(I), I=1,NDIM)} = 1 \ 0 \ 1 \ 0 \). The output

\begin{verbatim}
BR  PT  TY  LAB  PAR(1)   L2-NORM  MAX U(1) ... \\
1 15  UZ  2  1.700000E+00  3.836401E-01  4.890015E-01 ... \\
1 16  LP  3  1.711574E+00  3.922135E-01  5.442385E-01 ... \\
\end{verbatim}

178
Figure 21.1: $R_1$-Reversible homoclinic solutions on the half-interval $x/T \in [0,1]$ where $T = 39.0448429$ for $P$ approaching 2 (solutions with labels 1-5 respectively have decreasing amplitude)

Figure 21.2: $R_1$-reversible homoclinic orbits with oscillatory decay as $x \to -\infty$ (corresponding to label 6) and monotone decay (at label 10)
contains the label of a limit point \((\text{ILP} = 1)\) in \(c.\text{rev.3}\), which corresponds to a “coalescence” of two reversible homoclinic orbits. The two solutions on either side of this limit point are displayed in Figure 21.3. The computation ends in a no-convergence point. The solution here is depicted in Figure 21.4. The lack of convergence is due to the large peak and trough of the solution rapidly moving to the left as \(P \to -2\) (cf. Champneys & Spence (1993)).

Continuing from the initial solution in the other parameter direction

\[\textit{make fourth}\]

we obtain the output

\[
\begin{array}{cccccc}
\text{BR} & \text{PT} & \text{TY} & \text{LAB} & \text{PAR(1)} & \text{L2-NORM} \\
1 & 7 & \text{UZ} & 8 & 1.600000E+00 & 3.701709E-01 \\
1 & 33 & \text{UZ} & 9 & 9.999980E-01 & 3.614405E-01 \\
1 & 93 & \text{UZ} & 10 & -7.819855E-06 & 3.713007E-01 \\
\end{array}
\]

which again ends at a no convergence error for similar reasons.
Figure 21.3: Two $R_2$-reversible homoclinic orbits at $P = 1.6$ corresponding to labels $1$ (smaller amplitude) and $5$ (larger amplitude).

Figure 21.4: An $R_2$-reversible homoclinic orbit at label $8$.

Table 21.1: Detailed AUTO -Commands for running demo rev.
Chapter 22

HomCont Demo : Homoclinic branch switching.

This demo illustrates homoclinic branch switching, which is an implementation of Lin’s method (Lin 1990, Sandstede 1993, C. 2001) as described in Oldeman et al. (2001). We use a direct branch switching method to switch from 1- to 2- and 3-homoclinic orbits near an inclination flip bifurcation in a model due to Sandstede, which was introduced in Chapter 16. This also shows how to obtain a homoclinic orbit through continuation of a periodic orbit born at a Hopf bifurcation. Thereafter, we illustrate homoclinic branch switching for the FitzHugh-Nagumo equations and a 5th-order Korteweg-De Vries model.

22.1 Branch switching at an inclination flip in Sandstede’s model.

Consider the system (Sandstede 1995a)

\[
\begin{align*}
\dot{x} &= ax + by - ax^2 - azx(2 - 3x), \\
\dot{y} &= bx + ay - \frac{3}{2}x(bx + ay) + az2y, \\
\dot{z} &= cz + \mu x + 3xz + \alpha(x^2(1 - x) - y^2).
\end{align*}
\]

(22.1)
as given in the file sib.c, where for simplicity we have set \( \mu = 0, \beta = 1 \) and \( \gamma = 3 \).

We study an inclination flip that exists for \( a = 0.375, b = 0.625 \) and \( c = -0.75 \). This corresponds to the situation where the eigenvalues of the equilibrium at the origin are \( a + b = 1, a - b = -0.25 \) and \( c = -0.75 \). Hence, the corresponding bifurcation diagram consists of a complicated structure involving a fan of infinitely many \( n \)-periodic and \( n \)-homoclinic orbits for arbitrary \( n \) and a region with horseshoe dynamics; see also Homburg & Krauskopf (2000) and the references therein.

This computation starts from an equilibrium at \((2/3, 0, 0)\), which exists for \( a = \mu = \alpha = 0 \). Also, \( b \) is set to 0.625 (the value we would like it to be) and \( c \) is set to \(-2.5 \) in stpnt. Choosing \( c = -2 \) at this stage leads to convergence problems. This equilibrium is not the one corresponding to the homoclinic orbit, but it is an equilibrium with complex eigenvalues, that we can follow until it reaches a Hopf bifurcation. A periodic orbit emanates from this Hopf bifurcation and can be followed to the homoclinic orbit. However, first we need to change \( a \) from 0 to 0.375.

183
All the following commands, except for `demo('sib')` are contained within the file `sib.auto` which you can either execute in a batch mode by entering

```
> auto sib.auto
```
or step by step using

```
AUTO> demofile('sib.auto').
```

We start by copying the demo to the current work directory and running the first step

```
demo('sib')
ld('sib')
rn()
```

The equilibrium is followed in α until (or \(\text{PAR}(1)\)) is at our desired value, 0.375.

```
BR PT TY LAB PAR(1) ... U(1) U(2) U(3)
1 1 EP 1 0.000000E+00 ... 6.666667E-01 0.000000E+00 0.000000E+00
1 6 EP 2 3.750000E-01 ... 6.666667E-01 -1.333333E-01 0.000000E+00
```

The output is saved in the files `b.1`, `s.1` and `d.1`. Next we continue in α (\(\text{PAR}(4)\)) until a Hopf bifurcation is found:

```
rn(c='sib.2',s='1')
sv('2')
```

or, alternatively,

```
cc("IRS",2)
cc("ICP",[4])
rn(s='1')
sv('2')
```

```
BR PT TY LAB PAR(4) ... U(1) U(2) U(3)
1 18 HB 3 3.184290E-01 ... 6.543750E-01 -1.347543E-01 7.701025E-02
```

The output is saved in the files `b.2`, `s.2` and `d.2`. This Hopf bifurcation can then be continued into a periodic orbit. The periodic orbit eventually reaches a homoclinic bifurcation. We continue in \(\mu=\text{PAR}(5)\) and \(\text{PAR}(10)\), which corresponds to the period, and stop when the period is equal to 35.

```
rn(c='sib.3',s='2')
sv('3')
```

```
BR PT TY LAB PAR(5) L2-NORM ... PERIOD
3 5 5 -2.418809E-03 6.705689E-01 ... 1.089749E+01

```
The output is saved in the files b.3, s.3 and d.3. Note that \( \mu \) first decreases and then increases towards 0, which is precisely what we expect in this model, as homoclinic orbits occur on the line \( \mu = 0 \) in the \((\alpha, \mu)\)-plane. It is now instructive to look at a phase space diagram to see what is going on.

```
plot('3')
```

Selecting the diagram depicted in Figure 22.1(a), we have found an orbit.

![Diagram](image)

Figure 22.1: Periodic orbit growing from a Hopf bifurcation to a homoclinic orbit (a). The unshifted homoclinic orbit (b).

Note however, that the homoclinic orbit has the wrong left-hand and right-hand end points. This can be seen by plotting the solution corresponding to Label [13] using ‘t’ vs. ‘x’ (coordinate [0]), as depicted in Figure 22.1(b).

Hence, in order to continue this as a real homoclinic we have to give HomCont special instructions, to do a phase-shift in time. This can be done by setting \( \text{ISTART}=4 \). Moreover, since we have not specified the value of the equilibrium at the origin in \( \text{sib.c} \), we need to set \( \text{IEQUIB}=1 \) to let HomCont detect the equilibrium. Note that in this case this is not strictly necessary; however, we do this for instructional purposes.

Now we use HomCont to continue the homoclinic orbit in \( c \) and \( \mu \) (\( \text{PAR}(3), \text{PAR}(5) \)), to get the desired value \( c = -2.0 \).

```
\text{rn(c='sib.4',h='sib.shift',s='3')} \\
\text{sv('4')} \\
```

<table>
<thead>
<tr>
<th>BR</th>

<td>4.018899E-01</td>
<td>...</td>
<td>2.661459E-09</td>
</tr>
</tbody>
</table>

The output is saved in the files b.4, s.4 and d.4. Note that \( \text{PAR}(5)=\mu \) remains zero, which is exactly what we expect.
Next we want to add a solution to the adjoint equation to this solution. This is achieved by making the change \texttt{ITWIST = 1} saved in \texttt{h.sib.twist}. Also, we set \texttt{ISTART} to 1 to tell HomCont that it is should not try to shift the orbit anymore.

\begin{verbatim}
  rn(c='sib.5',h='sib.twist',s='4')
  sv('5')
\end{verbatim}

or, alternatively,

\begin{verbatim}
  cc("IRS",14)
  cc("ICP",[5,8])
  cc("NMX",2)
  chc("ITWIST",1)
  chc("ISTART",1)
  rn(s='4')
  sv('5')
\end{verbatim}

where \texttt{chc} means “change HomCont constant”. The output is stored in \texttt{b.5}, \texttt{s.5} and \texttt{d.5}.

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>

<td>2.550843E-09</td>
<td>4.018898E-01</td>
<td>...</td>
<td>-1.000000E-02</td>
</tr>
</tbody>
</table>

Here \texttt{PAR(8)} is a dummy (unused) parameter and \(\mu\) just stays where it is. Now that we have obtained the solution of the adjoint equation, we are able to detect inclination flips. This can be achieved by setting \texttt{NPSI} to 1, \texttt{IPSI(1)} to 13, and monitoring \texttt{PAR(32)}.

\begin{verbatim}
  rn(c='sib.6',h='sib.if',s='5')
  sv('6')
\end{verbatim}

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>

<td>4.018899E-01</td>
<td>...</td>
<td>1.243774E-11</td>
<td>-2.366987E-07</td>
</tr>
</tbody>
</table>

The output is stored in \texttt{b.6}, \texttt{s.6} and \texttt{d.6}. Hence an inclination flip was found at \(\alpha = 0.7117745\).

Now we are ready to perform homoclinic branch switching, using the techniques described in (Oldeman et al. 2001). Our first aim is to find a 2-homoclinic orbit. The ingredients we need are: a homoclinic orbit where \(n\)-homoclinic orbits are close by, and the solution to the adjoint equation to obtain the Lin vector. Since both ingredients are there, we can now continue in \(\mu\), \(\varepsilon_1\) and \(T_1\), to obtain the initial Lin gap. Recall from Chapter 15 that the Lin gaps \(\varepsilon_i\) correspond to \texttt{PAR(19+i*2)} and the time intervals \(T_i\) correspond to \texttt{PAR(20+i*2)}. We stop when \(\varepsilon_1 = 0.2\). We need to specify \texttt{ITWIST=2}, to tell HomCont we aim to find a 2-homoclinic orbit, so that it will split it up in three parts with two potential Lin gaps. We effectively have a 9-dimensional system at this point.

\begin{verbatim}
  rn(c='sib.7',h='sib.hbs2',s='6')
  sv('7')
\end{verbatim}
The output is appended to b.6, s.6 and d.6. Now we have obtained a 2-homoclinic orbit at label 24. However, the homoclinic orbit is still split in three parts. We can switch back to a normal orbit by setting ITWIST back to 0 and continuing in the usual way. Here we continue back to the inclination flip point in α and µ.

\[
\text{rn(c='sib.8',h='sib.hom',s='6')}
\]
\[
\text{ap('6')}\]

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>

Figure 22.2: Behaviour of the second piece of the ‘broken homoclinic orbit’ when creating a Lin gap (a). Projection of the “broken homoclinic orbit” onto the (x, y)-plane, where \( \varepsilon_1 = 0.2 \). To include all the pieces necessary to obtain this figure, the “X” box must contain [0,3,6] and the “Y” box must contain [1,4,7] (b).
So the 2-homoclinic orbit converges back to the 1-homoclinic orbit at the inclination flip bifurcation. The output is appended to \texttt{b.6, s.6 and d.6}. The resulting 2-homoclinic orbits can be seen using

\begin{verbatim}
ITWIST=3
\end{verbatim}

and is depicted in Figure 22.3(a).

Figure 22.3: The 2-homoclinic orbit as \(a\) is changed (a). The two different 3-homoclinic orbits (b).

Next, we aim to find a 3-homoclinic orbit. To do so, we restart at the inclination flip point at label 16 and set ITWIST=3. Moreover, we need to continue in one more gap, \(\varepsilon_2=\text{PAR(23)}\) and, once again, stop when \(\varepsilon_1=\text{PAR(21)}=0.2\). Note that the dimension of the boundary value problem we continue is now equal to 12. This is not to be confused with the setting of NDIM=3 in the parameter file, because HomCont handles this internally.

\begin{verbatim}
\texttt{rn(c=sib.10',h=sib.hbs3',s=’6’)}
\texttt{sv(’10’)}
\end{verbatim}

The output is stored in \texttt{b.10, s.10 and d.10}. Now we need to subsequently close the Lin gaps. Our strategy is to keep \(T_1\) fixed. We first continue in \(\alpha, \mu, \varepsilon_1\) and \(\varepsilon_2\) until \(\varepsilon_1 = 0\).

\begin{verbatim}
\texttt{rn(c=sib.11',h=sib.hbs3',s=’10’)}
\texttt{ap(’6’)}
\end{verbatim}
The output is appended to \texttt{b.6}, \texttt{s.6} and \texttt{d.6}. Note that this continuation is very similar to the one where we found a 2-homoclinic orbit. In fact we have now found a 2-homoclinic orbit (numerically) followed by a ‘broken’ 1-homoclinic orbit; only the mesh is not aligned.

The next step is to close the gap corresponding to \( \varepsilon_2 \) to obtain a 3-homoclinic orbit. We replace the continuation parameter \( \varepsilon_1 \) by \( T_2 \), because \( T_2 (\text{PAR}(22)) \) still has to be decreased from its high value (35) and \( \varepsilon_1 \) needs to stay at 0.

\[
\text{rn}(c='sib.12', h='sib.hbs3', s='6')
\]
\[
\text{ap('6')}
\]

The output is appended to \texttt{b.6}, \texttt{s.6} and \texttt{d.6}. Note that we have found two zeros of \text{PAR}(23), at labels 32 and 34, respectively. The two zeros correspond to two different 3-homoclinic orbits, which, when followed from periodic orbits, both emanate from from the same saddle-node bifurcation. These two 3-homoclinic orbits are depicted in Figure 22.3(b). We can follow both of these back to the inclination flip point, by setting \text{ITWIST} back to 0:

\[
\text{rn}(c='sib.13', h='sib.hom', s='6')
\]
\[
\text{ap('6')}
\]

All the output is appended to \texttt{b.6}, \texttt{s.6} and \texttt{d.6}. The bifurcation diagram and the paths we followed when closing the Lin gaps are depicted in Figure 22.4. It is possible and straightforward to obtain 4, 5, 6, \ldots-homoclinic orbits by extending the above strategy.
Figure 22.4: Parameter space diagram near an inclination flip. The curve through label 17 corresponds to a 1-homoclinic orbit. The opening of the Lin gaps occurs along the vertical line from label 16 to label 23. The curves through labels 23 and 30 denote the path that is followed when closing the Lin gaps. The (approximately overlaid) curves though labels 25 and 35 correspond to the 2- and one of the 3-homoclinic orbits. Finally, the curve through label 37 corresponds to the other 3-homoclinic orbit, which was obtained for \( \text{PAR}(22) = T_2 = 12.03201 \).

### 22.2 Branch switching for a Shil’nikov type homoclinic orbit in the FitzHugh-Nagumo equations.

The FitzHugh-Nagumo (FHN) equations (FitzHugh 1961, Nagumo, Arimoto & Yoshizawa 1962) are a simplified version of the Hodgkin-Huxley equations (Hodgkin & Huxley 1952). They model nerve axon dynamics and are given by

\[
\begin{align*}
    u_t &= u_{xx} - f_a(u) - w, \\
    w_t &= \epsilon(u - \gamma w),
\end{align*}
\]  
(22.2)

where

\[ f_a(u) = u(u - a)(u - 1). \]

Travelling wave solutions of the form \((u, w)(x, t) = (u, w)(\xi)\), where \(\xi = x + ct\) are solutions of the following ODE system:

\[
\begin{align*}
    \dot{u} &= v, \\
    \dot{v} &= cv + f_a(u) + w, \\
    \dot{w} &= \frac{\epsilon}{c}(u - \gamma w).
\end{align*}
\]  
(22.3)
In particular we consider solitary wave solutions of (22.2). These correspond to orbits homoclinic to \((u, v, w) = 0\) in system (22.3). In our numerical example we keep \(\gamma = 0\).

We aim to find a 2-homoclinic orbit at a Shil’nikov bifurcation. All the commands given here are in the file fnb.auto. First we obtain a homoclinic orbit using a homotopy technique (see Friedman, Doedel & Monteiro (1994)), using ISTART=3, for the parameter values \(c = 0.21, a = 0.2, \epsilon = 0.0025\).

\[
\text{demo('sib')}
\]
\[
\text{ld('fnb')}
\]
\[
\text{rn()}
\]
\[
\text{sv('1')}
\]

Among the output we see:

<table>
<thead>
<tr>
<th>BR</th>
<th>PT</th>
<th>TY</th>
<th>LAB</th>
<th>PERIOD</th>
<th>L2-NORM</th>
<th>...</th>
<th>PAR(16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>20</td>
<td>UZ</td>
<td>3</td>
<td>2.922565E+01</td>
<td>2.379162E-01</td>
<td>...</td>
<td>-1.680003E-09</td>
</tr>
</tbody>
</table>

and a zero of \(\text{PAR}(16)\) means that a zero of an artificial parameter has been located and the right-hand end point of the corresponding solution belongs to the plane that is tangent to the stable manifold at the saddle. This point still needs to come closer to the equilibrium, which we can achieve by further increasing the period to 300, while keeping \(\text{PAR}(16)\) at 0:

\[
\text{rn(c='fnb.2',h='fnb.1',s='1')}\]
\[
\text{sv('2')}\]

Next we stop using the homotopy technique and increase the period even further, to 1000.

\[
\text{rn(c='fnb.3',h='fnb.3',s='2')}\]
\[
\text{sv('3')}\]

A continuation in \(\text{PAR}(1) = a\) and \(\text{PAR}(0) = c\) needs to be performed to arrive at the place where we wish to find a 2-homoclinic orbit: \(a = 0\). At the same time we monitor \(\text{PAR}(21)\) to locate Belyakov points.

\[
\text{rn(c='fnb.4',h='fnb.4',s='3')}\]
\[
\text{sv('4')}\]

A continuation in \(\text{PAR}(1) = a\) and \(\text{PAR}(0) = c\) needs to be performed to arrive at the place where we wish to find a 2-homoclinic orbit: \(a = 0\). At the same time we monitor \(\text{PAR}(21)\) to locate Belyakov points.

\[
\text{rn(c='fnb.4',h='fnb.4',s='3')}\]
\[
\text{sv('4')}\]

191
Hence, there exists a Belyakov point at \((a, c) = (0.1318124, 0.217656)\). At label 19 we have a lower value of \(a\) than at the Belyakov point, and by inspection of the file d.4 we can observe that the equilibrium has one positive eigenvalue and a complex conjugate pair of eigenvalues with negative real part, and conclude that this orbit is of Shil’nikov type. Before starting the homoclinic branch switching, we calculate the adjoint to obtain a ‘Lin vector’:

\[
\begin{align*}
\text{rn}(c='fnb.5',h='fnb.5',s='4') \\
\text{sv}('5')
\end{align*}
\]

Next, we continue in the time \(T_1\) (PAR(20)), the gap \(\varepsilon_1\) (PAR(21)) and \(c\) (PAR(0)), and by setting \(\text{ISTART}=-2\) we try to locate a 2-homoclinic orbit:

\[
\begin{align*}
\text{rn}(c='fnb.6',h='fnb.6',s='5') \\
\text{sv}('6')
\end{align*}
\]

In fact we find many of them, exactly as is predicted by the theory:

\[
\begin{align*}
\text{BR} & \quad \text{PT} & \quad \text{TY} & \quad \text{LAB} & \quad \text{PAR}(8) & \quad \text{L2-NORM} & \quad \cdots & \quad \text{PAR}(2) \\
1 & 2 & EP & 28 & -1.000000E+00 & 1.561579E-02 & \cdots & 2.500000E-03
\end{align*}
\]

Each of these homoclinic orbits differ by about 20 in the value \(T_1\). This is about the time it takes to make one half-turn close to and around the equilibrium, so that orbits differ by the number of half turns around the equilibrium before a big excursion in phase space. Note that the variation of \(c\) is so small that it does not appear.

A plot of \(T_1\) vs. \(\varepsilon_1\) gives insight into how the gap is opened and closed in the continuation process. This is depicted in Figure 22.5. We are now in a position to continue each of these orbits as a normal homoclinic orbit by setting \(\text{ISTART}=1\) and \(\text{ITWIST}=0\). We leave this as an exercise to the reader.

### 22.3 Branch switching to a 3-homoclinic orbit in a 5th-order Korteweg-De Vries model

In Champneys & Groves (1997) the following water wave model was considered:

\[
\frac{2}{15} r''' - br'' + ar + \frac{3}{2} r^2 - \frac{1}{2} (r')^2 + [rr']' = 0. \quad (22.4)
\]
It represents solitary-wave solutions $r(x + at)$, $r \to 0$ as $x \to \pm\infty$ of the 5th-order PDE

$$rt + \frac{2}{15}r_{xxxx} - br_{xxx} + 3rr_x + 2rr_{xx} + rr_{xxx} = 0,$$

where $a$ is the wave speed. The ODE corresponds to a Hamiltonian system with Hamiltonian

$$H = -\frac{1}{2}q_1^3 - \frac{1}{2}aq_1^2 + p_1q_2 - \frac{1}{2}bq_2^2 + \frac{15}{4}p_2^2 + \frac{1}{2}q_2^2q_1$$

and

$$q_1 = r, \quad q_2 = r', \quad p_1 = -\frac{2}{15}r''' + br' - rr', \quad p_2 = \frac{2}{15}r''.$$

System (22.4) is also reversible under the transformation

$$t \mapsto -t, \quad (q_1, q_2, p_1, p_2) \mapsto (q_1, -q_2, -p_1, p_2),$$

but we do not exploit the reversible structure (IREV=0), and instead use it as an example of Hamiltonian system. This system exhibits an orbit flip for a reversible Hamiltonian system. In Hamiltonian systems, homoclinic orbits are codimension-zero phenomena, and we have to add an additional parameter $\lambda$ that breaks the Hamiltonian structure in this system, by introducing artificial friction. Thus, the actual system of equations that is used for continuation is

$$\dot{x} = (\lambda I + J)\nabla H(x),$$

where $x = (q_1, q_2, p_1, p_2)$ and $J$ is the usual skew symmetric matrix in $\mathbb{R}^4$. It is now possible to continue a homoclinic orbit in HomCont in two parameters ($\lambda$ and either $a$ or $b$); see also Beyn (1990).
An explicit solution exists for $a = 3/5(2b + 1)(b - 2), b \geq -1/2$, and it is given by
\[
r(t) = 3(b + 1/2) \text{sech}^2 \left( \frac{3}{4} (2b + 1)^{1/2} t \right).
\]
It corresponds to a reversible orbit flip for $b > 2$ ($a > 0$). We start from this explicit solution, using $\text{ISTART}=2$, for $a = 3$ and $b = (\sqrt{65} + 3)/4$:
\[
\text{demo('kdv')}
\]
\[
\text{id('kdv')}
\]
\[
\text{rn()}
\]
\[
\text{sv('1')}
\]

Here $\text{PAR(0)}=a$, $\text{PAR(1)}=b$, and $\text{PAR(2)}=\lambda$. We have only done a very small continuation to give AUTO a chance to create a good mesh and avoid convergence problems later. Next, we set $\text{ITWIST}=1$ and calculate the adjoint:
\[
\text{rn(c='kdv.2',h='kdv.2',s='1')}
\]
\[
\text{sv('2')}
\]

We now need to move back to the orbit flip at $a = 3$:
\[
\text{rn(c='kdv.3',h='kdv.3',s='2')}
\]
\[
\text{sv('3')}
\]

Now all preparations are done to start homoclinic branch switching. This is very similar to the technique used in Sandstede’s model in Section 22.1; to find a 3-homoclinic orbit, we open 2 Lin gaps, until $T_1 = 3.5$, while also varying $\lambda=\text{PAR(2)}$.
\[
\text{rn(c='kdv.4',h='kdv.4',s='3')}
\]
\[
\text{sv('4')}
\]
We then look for an orbit with $a < 3$ and close the gap corresponding to $\varepsilon_1 = \text{PAR}(21)$, for decreasing $a$.

\[
\begin{align*}
\text{rn}(c='kdv.5', h='kdv.5', s='4') \\
\text{sv('5')} \\
\end{align*}
\]

</tbody>
</table>

so that a three-homoclinic orbit is found. Here the zero at label 17 is the one we are looking for. Label 15 is a false positive since $T_2 = \text{PAR}(22)$ is still too high. At label 18, $a = \text{PAR}(1)$ has changed considerably to the extend that $a > 3$ and a second 3-homoclinic orbit is found. Note that for all zeros of $\text{PAR}(23) = \varepsilon_2$, the parameter $\lambda = \text{PAR}(2)$ is also zero (within AUTO accuracy), which it has to be to remain within the original Hamiltonian system. Setting $\text{ISTART}=1$, a normal “trivial” continuation (with $\text{NMX}=1$) of the orbit corresponding to label 17 lets HomCont produce a proper concatenated 3-homoclinic orbit:

\[
\begin{align*}
\text{rn}(c='kdv.7', h='kdv.7', s='6') \\
\text{sv('7')} \\
\end{align*}
\]

<table>

<td>2</td>
<td>EP</td>
<td>20</td>
<td>2.336952E+00</td>
<td>7.505830E+00</td>
</tr>
</tbody>
</table>

This 3-homoclinic orbit is depicted in Figure 22.6.
Figure 22.6: A 3-homoclinic orbit in a 5th-order Hamiltonian Korteweg-De Vries model.
Appendix A

Running AUTO using Command Mode.

AUTO can be run with the interface described in Chapter 4 or with the commands described below. The AUTO aliases must have been activated; see Section 1.2; and an equations-file xxx.c and a corresponding constants-file c.xxx (see Section 3.1) must be in the current user directory. Do not run AUTO in the directory auto/2000 or in any of its subdirectories.

A.0.1 Basic commands.

@r : Type @r xxx to run AUTO. Restart data, if needed, are expected in s.xxx, and AUTO -constants in c.xxx. This is the simplest way to run AUTO.

- Type @r xxx yyy to run AUTO with equations-file xxx.c and restart data-file s.yyy. AUTO -constants must be in c.xxx.

- Type @r xxx yyy zzz to run AUTO with equations-file xxx.c, restart data-file s.yyy and constants-file c.zzz.

@R : The command @R xxx is equivalent to the command @r xxx above.

- Type @R xxx i to run AUTO with equations-file xxx.c, constants-file c.xxx.i and, if needed, restart data-file s.xxx.

- Type @R xxx i yyy to run AUTO with equations-file xxx.c, constants-file c.xxx.i and restart data-file s.yyy.

@sv : Type @sv xxx to save the output-files fort.7, fort.8, fort.9, as b.xxx, s.xxx, d.xxx, respectively. Existing files by these names will be deleted.

@ap : Type @ap xxx to append the output-files fort.7, fort.8, fort.9, to existing data-files b.xxx, s.xxx, d.xxx, resp.

- Type @ap xxx yyy to append b.xxx, s.xxx, d.xxx, to b.yyy, s.yyy, d.yyy, resp.
A.0.2 Plotting commands.

@p : Type @p xxx to run the graphics program PLAUT (See Chapter B) for the graphical inspection of the data-files b.xxx and s.xxx.

- Type @p to run the graphics program PLAUT for the graphical inspection of the output-files fort.7 and fort.8.

@ps : Type @ps fig.x to convert a saved PLAUT figure fig.x from compact PLOT10 format to PostScript format. The converted file is called fig.x. The original file is left unchanged.

@pr : Type @pr fig.x to convert a saved PLAUT figure fig.x from compact PLOT10 format to PostScript format and send it to the printer. The converted file is called fig.x. The original file is left unchanged.

A.0.3 File-manipulation.

@cp : Type @cp xxx yyy to copy the data-files b.xxx, s.xxx, d.xxx, c.xxx to b.yyy, s.yyy, d.yyy, c.yyy, respectively.

@mv : Type @mv xxx yyy to move the data-files b.xxx, s.xxx, d.xxx, c.xxx, to b.yyy, s.yyy, d.yyy, c.yyy, respectively.

@df : Type @df to delete the output-files fort.7, fort.8, fort.9.

@cl : Type @cl to clean the current directory. This command will delete all files of the form fort.*, *.o, and *.exe.

@dl : Type @dl xxx to delete the data-files b.xxx, s.xxx, d.xxx.

A.0.4 Diagnostics.

@lp : Type @lp to list the value of the “limit point function” in the output-file fort.9. This function vanishes at a limit point (fold).

- Type @lp xxx to list the value of the “limit point function” in the data-file d.xxx. This function vanishes at a limit point (fold).

@bp : Type @bp to list the value of the “branch-point function” in the output-file fort.9. This function vanishes at a branch point.

- Type @bp xxx to list the value of the “branch-point function” in the data-file d.xxx. This function vanishes at a branch point.

@hb : Type @hb to list the value of the “Hopf function” in the output-file fort.9. This function vanishes at a Hopf bifurcation point.

- Type @hb xxx to list the value of the “Hopf function” in the data-file d.xxx. This function vanishes at a Hopf bifurcation point.
@sp : Type @sp to list the value of the “secondary-periodic bifurcation function” in the output-file fort.9. This function vanishes at period-doubling and torus bifurcations.

- Type @sp xxx to list the value of the “secondary-periodic bifurcation function” in the data-file d.xxx. This function vanishes at period-doubling and torus bifurcations.

@it : Type @it to list the number of Newton iterations per continuation step in fort.9.

- Type @it xxx to list the number of Newton iterations per continuation step in d.xxx.

@st : Type @st to list the continuation step size for each continuation step in fort.9.

- Type @st xxx to list the continuation step size for each continuation step in d.xxx.

@ev : Type @ev to list the eigenvalues of the Jacobian in fort.9. (Algebraic problems.)

- Type @ev xxx to list the eigenvalues of the Jacobian in d.xxx. (Algebraic problems.)

@fl : Type @fl to list the Floquet multipliers in the output-file fort.9. (Differential equations.)

- Type @fl xxx to list the Floquet multipliers in the data-file d.xxx. (Differential equations.)

### A.0.5 File-editing.

@e7 : To use the vi editor to edit the output-file fort.7.

@e8 : To use the vi editor to edit the output-file fort.8.

@e9 : To use the vi editor to edit the output-file fort.9.

@j7 : To use the SGI jot editor to edit the output-file fort.7.

@j8 : To use the SGI jot editor to edit the output-file fort.8.

@j9 : To use the SGI jot editor to edit the output-file fort.9.

### A.0.6 File-maintenance.

@lb : Type @lb to run an interactive utility program for listing, deleting and relabeling solutions in the output-files fort.7 and fort.8. The original files are backed up as ~fort.7 and ~fort.8.

- Type @lb xxx to list, delete and relabel solutions in the data-files b.xxx and s.xxx. The original files are backed up as ~b.xxx and ~s.xxx.

- Type @lb xxx yyy to list, delete and relabel solutions in the data-files b.xxx and s.xxx. The modified files are written as b.yyy and s.yyy.
@fc : Type @fc xxx to convert a user-supplied data file xxx.dat to AUTO format. The converted file is called s.dat. The original file is left unchanged. AUTO automatically sets the period in PAR(11). Other parameter values must be set in stpnt. (When necessary, PAR(11) may also be redefined there.) The constants-file file c.xxx must be present, as the AUTO -constants NTST and NCOL (Sections 5.3.1 and 5.3.2) are used to define the new mesh. For examples of using the @fc command see demos lor and pen.

@94to97 : Type @94to97 xxx to convert an old AUTO 94 data-file s.xxx to new AUTO 97 format. The original file is backed up as ∼s.xxx. This conversion is only necessary for files from early versions of AUTO 94.

A.0.7 HomCont commands.

@h : Use @h instead of @r when using HomCont, i.e., when IPS=9 (see Chapter 15). Type @h xxx to run AUTO /HomCont. Restart data, if needed, are expected in s.xxx, AUTO -constants in c.xxx and HomCont-constants in h.xxx.

- Type @h xxx yyy to run AUTO /HomCont with equations-file xxx.c and restart data-file s.yyy. AUTO -constants must be in c.xxx and HomCont-constants in h.xxx.

- Type @h xxx yyy zzz to run AUTO /HomCont with equations-file xxx.c, restart data-file s.yyy and constants-files c.zzz and h.zzz.

@H : The command @H xxx is equivalent to the command @h xxx above.

- Type @H xxx i in order to run AUTO /HomCont with equations-file xxx.c and constants-files c.xxx.i and h.xxx.i and, if needed, restart data-file s.xxx.

- Type @H xxx i yyy to run AUTO /HomCont with equations-file xxx.c, constants-files c.xxx.i and h.xxx.i, and restart data-file s.yyy.

A.0.8 Copying a demo.

@dm : Type @dm xxx to copy all files from auto/2000/demos/xxx to the current user directory. Here xxx denotes a demo name; e.g., abc. Note that the @dm command also copies a Makefile to the current user directory. To avoid the overwriting of existing files, always run demos in a clean work directory.

A.0.9 Pendula animation.

@pn : Type @pn xxx to run the pendula animation program with data-file s.xxx. (On SGI machine only; see demo pen in Section 9.10 and the file auto/2000/pendula/README.)

A.0.10 Viewing the manual.

@mn : Use Ghostview to view the PostScript version of this manual.
Appendix B

The Graphics Program PLAUT.

PLAUT can be used to extract graphical information from the AUTO output-files `fort.7` and `fort.8`, or from the corresponding data-files `b.xxx` and `s.xxx`. To invoke PLAUT, use the the `@p` command defined in Section A. The PLAUT window (a Tektronix window) will appear, in which PLAUT commands can be entered. FIXME: This is not correct anymore For examples of using PLAUT see the tutorial demo `ab`, in particular, Sections 7.7 and 7.10. See also demo `pp2` in Section 9.3.

B.1 Basic PLAUT-Commands.

The principal PLAUT-commands are

`bd0`: This command is useful for an initial overview of the bifurcation diagram as stored in `fort.7`. If you have not previously selected one of the default options `d0`, `d1`, `d2`, `d3`, or `d4` described below then you will be asked whether you want solution labels, grid lines, titles, or labeled axes.

`bd`: This command is the same as the `bd0` command, except that you will be asked to enter the minimum and the maximum of the horizontal and vertical axes. This is useful for blowing up portions of a previously displayed bifurcation diagram.

`ax`: With the `ax` command you can select any pair of columns of real numbers from `fort.7` as horizontal and vertical axis in the bifurcation diagram. (The default is columns 1 and 2). To determine what these columns represent, one can look at the screen output of the corresponding AUTO run, or one can inspect the column headings in `fort.7`.

`2d`: Upon entering the `2d` command, the labels of all solutions stored in `fort.8` will be listed and you can select one or more of these for display. The number of solution components is also listed and you will be prompted to select two of these as horizontal and vertical axis in the display. Note that the first component is typically the independent time or space variable scaled to the interval `[0,1]`.

`sav`: To save the displayed plot in a file. You will be asked to enter a file name. Each plot must be stored in a separate new file. The plot is stored in compact PLOT10 format,
which can be converted to PostScript format with the AUTO -commands @ps and @pr; see Section B.4.

c1 : To clear the graphics window.

lab : To list the labels of all solutions stored in fort.8. Note that PLAUT requires all labels to be distinct. In case of multiple labels you can use the AUTO command @lb to relabel solutions in fort.7 and fort.8.

end : To end execution of PLAUT.

B.2 Default Options.

After entering the commands bd0, bd, or 2d, you will be asked whether you want solution labels, grid lines, titles, or axes labels. For quick plotting it is convenient to bypass these selections. This can be done by the default commands d0, d1, d2, d3, or d4 below. These can be entered as a single command or they can be entered as prefixes in the bd0 and bd commands. Thus, for example, one can enter the command d1bd0.

d0 : Use solid curves, showing solution labels and symbols.

d1 : Use solid curves, except use dashed curves for unstable solutions and for solutions of unknown stability. Show solution labels and symbols.

d2 : As d1, but with grid lines.

d3 : As d1, except for periodic solutions use solid circles if stable, and open circles if unstable or if the stability is unknown.

d4 : Use solid curves, without labels and symbols.

If no default option d0, d1, d2, d3, or d4 has been selected or if you want to override a default feature, then the the following commands can be used. These can be entered as individual commands or as prefixes. For example, one can enter the command sydpbd0.

sy : Use symbols for special solution points, for example, open square = branch point, solid square = Hopf bifurcation.

dp : “Differential Plot”, i.e., show stability of the solutions. Solid curves represent stable solutions. Dashed curves are used for unstable solutions and for solutions of unknown stability. For periodic solutions use solid/open circles to indicate stability/instability (or unknown stability).

st : Set up titles and axes labels.

nu : Normal usage (reset special options).
B.3 Other PLAUT-Commands.

The full PLAUT program has several other capabilities, for example,

\texttt{scr} : To change the diagram size.

\texttt{rss} : To change the size of special solution point symbols.

B.4 Printing PLAUT Files.

\texttt{@ps} : Type \texttt{@ps fig.1} to convert a saved PLAUT file \texttt{fig.1} to PostScript format in \texttt{fig.1}.

\texttt{@pr} : Type \texttt{@pr fig.1} to convert a PLAUT file \texttt{fig.1} to PostScript format and to print the resulting file \texttt{fig.1}.
Appendix C

Graphical User Interface.

C.1 General Overview.

*Please note:* as of March 17, 2006 the GUI is being updated, so the documentation is this chapter is not being actively maintained. The old GUI is provided with this release of AUTO, but it is unsupported and may not be included in future releases.

The AUTO 97 graphical user interface (GUI) is a tool for creating and editing equations-files and constants-files; see Section 3.1 for a description of these files. The GUI can also be used to run AUTO and to manipulate and plot output-files and data-files; see Section A for corresponding commands. To use the GUI for a new equation, change to an empty work directory. For an existing equations-file, change to its directory. (*Do not activate the GUI in the directory auto/2000 or in any of its subdirectories.*) Then type

```
@ auto,
```

or its abbreviation @ a. Here we assume that the AUTO aliases have been activated; see Section 1.2. The GUI includes a window for editing the equations-file, and four groups of buttons, namely, the Menu Bar at the top of the GUI, the Define Constants-buttons at the center-left, the Load Constants-buttons at the lower left, and the Stop- and Exit-buttons.

*Note:* Most GUI buttons are activated by point-and-click action with the left mouse button. If a beep sound results then the right mouse button must be used.

C.1.1 The Menu bar.

It contains the main buttons for running AUTO and for manipulating the equations-file, the constants-file, the output-files, and the data-files. In a typical application, these buttons are used from left to right. First the Equations are defined and, if necessary, Edited, before being Written. Then the AUTO -constants are Defined. This is followed by the actual Run of AUTO. The resulting output-files can be Saved as data-files, or they can be Appended to existing data-files. Data-files can be Plotted with the graphics program PLAUT, and various file operations can be done with the Files-button. Auxiliary functions are provided by the Demos-, Misc-, and Help-buttons. The Menu Bar buttons are described in more detail in Section C.2.
C.1.2 The Define-Constants-buttons.

These have the same function as the Define-button on the Menu Bar, namely to set and change AUTO-constants. However, for the Define-button all constants appear in one panel, while for the Define Constants-buttons they are grouped by function, as in Chapter 5, namely Problem definition constants, Discretization constants, convergence Tolerances, continuation Step Size, diagram Limits, designation of free Parameters, constants defining the Computation, and constants that specify Output options.

C.1.3 The Load-Constants-buttons.

The Previous-button can be used to load an existing AUTO-constants file. Such a file is also loaded, if it exists, by the Equations-button on the Menu Bar. The Default-button can be used to load default values of all AUTO-constants. Custom editing is normally necessary.

C.1.4 The Stop- and Exit-buttons.

The Stop-button can be used to abort execution of an AUTO-run. This should be done only in exceptional circumstances. Output-files, if any, will normally be incomplete and should be deleted. Use the Exit-button to end a session.

C.2 The Menu Bar.

C.2.1 Equations-button.

This pull-down menu contains the items Old, to load an existing equations-file, New, to load a model equations-file, and Demo, to load a selected demo equations-file. Equations-file names are of the form xxx.c. The corresponding constants-file c.xxx is also loaded if it exists. The equation name xxx remains active until redefined.

C.2.2 Edit-button.

This pull-down menu contains the items Cut and Copy, to be performed on text in the GUI window highlighted by click-and-drag action of the mouse, and the item Paste, which places editor buffer text at the location of the cursor.

C.2.3 Write-button.

This pull-down menu contains the item Write, to write the loaded files xxx.c and c.xxx, by the active equation name, and the item Write As to write these files by a selected new name, which then becomes the active name.
C.2.4 Define-button.

Clicking this button will display the full AUTO -constants panel. Most of its text fields can be edited, but some have restricted input values that can be selected with the right mouse button. Some text fields will display a subpanel for entering data. To actually apply changes made in the panel, click the OK- or Apply-button at the bottom of the panel.

C.2.5 Run-button.

Clicking this button will write the constants-file c.xxx and run AUTO . If the equations-file has been edited then it should first be rewritten with the Write-button.

C.2.6 Save-button.

This pull-down menu contains the item Save, to save the output-files fort.7 , fort.8 , fort.9 , as b.xxx , s.xxx , d.xxx , respectively. Here xxx is the active equation name. It also contains the item Save As, to save the output-files under another name. Existing data-files with the selected name, if any, will be overwritten.

C.2.7 Append-button.

This pull-down menu contains the item Append, to append the output-files fort.7 , fort.8 , fort.9 , to existing data-files b.xxx , s.xxx , d.xxx , respectively. Here xxx is the active equation name. It also contains the item Append To, to append the output-files to other existing data-files.

C.2.8 Plot-button.

This pull-down menu contains the items Plot, to run the plotting program PLAUT for the data-files b.xxx and s.xxx , where xxx is the active equation name, and the item Name, to run PLAUT with other data-files.

C.2.9 Files-button.

This pull-down menu contains the item Restart, to redefine the restart file. Normally, when restarting from a previously computed solution, the restart data is expected in the file s.xxx , where xxx is the active equation name. Use the Restart-button to read the restart data from another data-file in the immediately following run. The pull-down menu also contains the following items:

- Copy, to copy b.xxx , s.xxx , d.xxx , c.xxx , to b.yyy , s.yyy , d.yyy , c.yyy , resp.;
- Append, to append data-files b.xxx , s.xxx , d.xxx , to b.yyy , s.yyy , d.yyy , resp.;
- Move, to move b.xxx , s.xxx , d.xxx , c.xxx , to b.yyy , s.yyy , d.yyy , c.yyy , resp.;
- Delete, to delete data-files b.xxx , s.xxx , d.xxx ;
- Clean, to delete all files of the form fort.*, *.o, and *.exe.
C.2.10 Demos-button.

This pulldown menu contains the items Select, to view and run a selected AUTO demo in the demo directory, and Reset, to restore the demo directory to its original state. Note that demo files can be copied to the user work directory with the Equations/Demo-button.

C.2.11 Misc.-button.

This pulldown menu contains the items Tek Window and VT102 Window, for opening windows; Emacs and Xedit, for editing files, and Print, for printing the active equations-file xxx.c.

C.2.12 Help-button.

This pulldown menu contains the items AUTO -constants, for help on AUTO -constants, and User Manual, for viewing the user manual; i.e., this document.

C.3 Using the GUI.

AUTO -commands are described in Section A and illustrated in the demos. In Table C.1 we list the main AUTO -commands together with the corresponding GUI button.

<table>
<thead>
<tr>
<th>Command</th>
<th>GUI Button</th>
</tr>
</thead>
<tbody>
<tr>
<td>@r</td>
<td>Run</td>
</tr>
<tr>
<td>@sv</td>
<td>Save</td>
</tr>
<tr>
<td>@ap</td>
<td>Append</td>
</tr>
<tr>
<td>@p</td>
<td>Plot</td>
</tr>
<tr>
<td>@cp</td>
<td>Files/Copy</td>
</tr>
<tr>
<td>@mv</td>
<td>Files/Move</td>
</tr>
<tr>
<td>@cl</td>
<td>Files/Clean</td>
</tr>
<tr>
<td>@dl</td>
<td>Files/Delete</td>
</tr>
<tr>
<td>@dm</td>
<td>Equations/Demo</td>
</tr>
</tbody>
</table>

Table C.1: Command Mode - GUI correspondences.

The AUTO -command @r xxx yyy is given in the GUI as follows: click Files/Restart and enter yyy as data. Then click Run. As noted in Section A, this will run AUTO with the current equations-file xxx.c and the current constants-file c.xxx, while expecting restart data in s.yyy. The AUTO -command @ap xxx yyy is given in the GUI by clicking Files/Append.

C.4 Customizing the GUI.

C.4.1 Print-button.

The Misc/Print-button on the Menu Bar can be customized by editing the file GuiConsts.h in directory auto/2000/include.
C.4.2 GUI colors.

GUI colors can be customized by creating an X resource file. Two model files can be found in directory `auto/2000/gui`, namely, `Xdefaults.1` and `Xdefaults.2`. To become effective, edit one of these, if desired, and copy it to `.Xdefaults` in your home directory. Color names can often be found in the system file `/usr/lib/X11/rgb.txt`.

C.4.3 On-line help.

The file `auto/2000/include/GuiGlobal.h` contains on-line help on AUTO -constants and demos. The text can be updated, subject to a modifiable maximum length. On SGI machines this is 10240 bytes, which can be increased, for example, to 20480 bytes, by replacing the line `CC = cc -Wf, -XNl10240 -O` in `auto/2000/gui/Makefile` by `CC = cc -Wf, -XNl20480 -O` On other machines, the maximum message length is the system defined maximum string literal length.
Bibliography
